Features

CPU Features

- Operating Voltage: \( f_{\text{SYS}} = 8\text{MHz} \): 2.2V~5.5V
- Up to 0.5\(\mu\text{s} \) instruction cycle with 8MHz system clock at \( V_{\text{DD}} = 5\text{V} \)
- Power down and wake-up functions to reduce power consumption
- Oscillator Types
  - Internal High Speed RC – HIRC
  - Internal 32kHz RC – LIRC
- Fully integrated internal 8MHz oscillator requires no external components
- Multi-mode operation: NORMAL, SLOW, IDLE and SLEEP
- All instructions executed in one to three instruction cycles
- Table read instructions
- 63 powerful instructions
- 2-level subroutine nesting
- Bit manipulation instruction

Peripheral Features

- Program Memory: 1K\(\times\)14
- Data Memory: 32\(\times\)8
- True EEPROM Memory: 32\(\times\)8
- Watchdog Timer function
- 6 bidirectional I/O lines
- Multiple Timer Modules for time measure, input capture, compare match output, PWM output function or single pulse output function
- One comparator with hysteresis control and interrupt generation
- One operational amplifier with gain control
- One 6-bit D/A converter
- Debounce circuit for comparator output with interrupt generation
- Dual Time-Base functions for generation of fixed time interrupt signals
- Low voltage reset function
- Flash program memory can be re-programmed up to 10,000 times
- Flash program memory data retention > 10 years
- True EEPROM data memory can be re-programmed up to 100,000 times
- True EEPROM data memory data retention > 10 years
- Package types: 8-pin SOP
General Description

The device is a Flash Memory type 8-bit high performance RISC architecture microcontroller with fully integrated Shock Sensor which is designed for various product applications. Offering users the convenience of Flash memory multi-programming features, the device also includes a wide range of functions and features. In addition to the flash program memory, other memory includes areas of RAM Data memory and true EEPROM Data memory.

Analog features include a 6-bit DAC, a comparator and an Operational Amplifier. Multiple and extremely flexible Timer Modules provide timing, pulse generation and PWM generation functions. The inclusion of flexible I/O programming features, Time Base functions together with many other features further enhance device functionality. Protective features such as an internal Watchdog Timer and Low Voltage Reset coupled with excellent noise immunity and ESD protection ensure that reliable operation is maintained in hostile electrical environments.

A full choice of HIRC and LIRC oscillator functions are provided including a fully integrated system oscillator. The ability to operate and switch dynamically between a range of operating modes using different clock sources gives users the ability to optimise microcontroller operation and minimise power consumption.

Block Diagram

Pin Assignment

Note: The OCDSDA and OCDSCK pins are the OCDS dedicated pins and only available for the HT45V56 device which is the OCDS EV chip for the HT45F56 device.
Pin Descriptions

With the exception of the power pins and some relevant transformer control pins, all pins on these devices can be referenced by their Port name, e.g. PA.0, PA.1 etc, which refer to the digital I/O function of the pins. However these Port pins are also shared with other function such as the Analog to Digital Converter, Timer Module pins etc. The function of each pin is listed in the following table, however the details behind how each pin is configured is contained in other sections of the datasheet.

Absolute Maximum Ratings

Supply Voltage .......................................................... $V_{SS} - 0.3V$ to $V_{SS} + 6.0V$
Input Voltage .......................................................... $V_{SS} - 0.3V$ to $V_{DD} + 0.3V$
Storage Temperature ........................................... $-50^\circ C$ to $125^\circ C$
Operating Temperature .......................................... $-40^\circ C$ to $85^\circ C$
$I_{OL}$ Total .......................................................... $80mA$
$I_{OH}$ Total .......................................................... $-80mA$
Total Power Dissipation ................................................. $500mW$

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to these devices. Functional operation of these devices at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect devices reliability.

**System Architecture**

A key factor in the high-performance features of the Holtek range of microcontrollers is attributed to their internal system architecture. The range of devices take advantage of the usual features found within RISC microcontrollers providing increased speed of operation and enhanced performance. The pipelining scheme is implemented in such a way that instruction fetching and instruction execution are overlapped, hence instructions are effectively executed in one cycle, with the exception of branch or call instructions. An 8-bit wide ALU is used in practically all instruction set operations, which carries out arithmetic operations, logic operations, rotation, increment, decrement, branch decisions, etc. The internal data path is simplified by moving data through the Accumulator and the ALU. Certain internal registers are implemented in the Data Memory and can be directly or indirectly addressed. The simple addressing methods of these registers along with additional architectural features ensure that a minimum of external components is required to provide a functional I/O and A/D control system with maximum reliability and flexibility. This makes these devices suitable for low-cost, high-volume production for controller applications.

**Clocking and Pipelining**

The main system clock, derived from either a HIRC or LIRC oscillator is subdivided into four internally generated non-overlapping clocks, T1~T4. The Program Counter is incremented at the beginning of the T1 clock during which time a new instruction is fetched. The remaining T2~T4 clocks carry out the decoding and execution functions. In this way, one T1~T4 clock cycle forms one instruction cycle. Although the fetching and execution of instructions takes place in consecutive instruction cycles, the pipelining structure of the microcontroller ensures that instructions are effectively executed in one instruction cycle. The exception to this are instructions where the contents of the Program Counter are changed, such as subroutine calls or jumps, in which case the instruction will take one more instruction cycle to execute.

For instructions involving branches, such as jump or call instructions, two machine cycles are required to complete instruction execution. An extra cycle is required as the program takes one cycle to first obtain the actual jump or call address and then another cycle to actually execute the branch. The requirement for this extra cycle should be taken into account by programmers in timing sensitive applications.
Instruction Fetching

Program Counter

During program execution, the Program Counter is used to keep track of the address of the next instruction to be executed. It is automatically incremented by one each time an instruction is executed except for instructions, such as “JMP” or “CALL” that demand a jump to a non-consecutive Program Memory address. Only the lower 8 bits, known as the Program Counter Low Register, are directly addressable by the application program.

When executing instructions requiring jumps to non-consecutive addresses such as a jump instruction, a subroutine call, interrupt or reset, etc., the microcontroller manages program control by loading the required address into the Program Counter. For conditional skip instructions, once the condition has been met, the next instruction, which has already been fetched during the present instruction execution, is discarded and a dummy cycle takes its place while the correct instruction is obtained.

The lower byte of the Program Counter, known as the Program Counter Low register or PCL, is available for program control and is a readable and writeable register. By transferring data directly into this register, a short program jump can be executed directly; however, as only this low byte is available for manipulation, the jumps are limited to the present page of memory that is 256 locations. When such program jumps are executed it should also be noted that a dummy cycle will be inserted. Manipulating the PCL register may cause program branching, so an extra cycle is needed to pre-fetch.
Stack

This is a special part of the memory which is used to save the contents of the Program Counter only. The stack has multiple levels and is neither part of the data nor part of the program space, and is neither readable nor writeable. The activated level is indexed by the Stack Pointer, and is neither readable nor writeable. At a subroutine call or interrupt acknowledge signal, the contents of the Program Counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction, RET or RETI, the Program Counter is restored to its previous value from the stack. After a device reset, the Stack Pointer will point to the top of the stack.

If the stack is full and an enabled interrupt takes place, the interrupt request flag will be recorded but the acknowledge signal will be inhibited. When the Stack Pointer is decremented, by RET or RETI, the interrupt will be serviced. This feature prevents stack overflow allowing the programmer to use the structure more easily. However, when the stack is full, a CALL subroutine instruction can still be executed which will result in a stack overflow. Precautions should be taken to avoid such cases which might cause unpredictable program branching.

If the stack is overflow, the first Program Counter save in the stack will be lost.

Arithmetic and Logic Unit – ALU

The arithmetic-logic unit or ALU is a critical area of the microcontroller that carries out arithmetic and logic operations of the instruction set. Connected to the main microcontroller data bus, the ALU receives related instruction codes and performs the required arithmetic or logical operations after which the result will be placed in the specified register. As these ALU calculation or operations may result in carry, borrow or other status changes, the status register will be correspondingly updated to reflect these changes. The ALU supports the following functions:

- Arithmetic operations:
  ADD, ADDM, ADC, ADCM, SUB, SUBM, SBC, SBCM, DAA

- Logic operations:
  AND, OR, XOR, ANDM, ORM, XORM, CPL, CPLA

- Rotation:
  RRA, RR, RRCA, RRC, RLA, RL, RLCA, RLC

- Increment and Decrement:
  INCA, INC, DECA, DEC

- Branch decision:
  JMP, SZ, SZA, SNZ, SIZ, SDZ, SIZA, SDZA, CALL, RET, RETI
Flash Program Memory

The Program Memory is the location where the user code or program is stored. For the device the Program Memory is Flash type, which means it can be programmed and re-programmed a large number of times, allowing the user the convenience of code modification on the same device. By using the appropriate programming tools, these Flash devices offer users the flexibility to conveniently debug and develop their applications while also offering a means of field programming and updating.

Structure

The Program Memory has a capacity of 1K×14 bits. The Program Memory is addressed by the Program Counter and also contains data, table information and interrupt entries. Table data, which can be setup in any location within the Program Memory, is addressed by a separate table pointer registers.

![Program Memory Structure]

Special Vectors

Within the Program Memory, certain locations are reserved for the reset and interrupts. The location 000H is reserved for use by these devices reset for program initialisation. After a device reset is initiated, the program will jump to this location and begin execution.

Look-up Table

Any location within the Program Memory can be defined as a look-up table where programmers can store fixed data. To use the look-up table, the table pointer must first be setup by placing the address of the look up data to be retrieved in the table pointer register, TBLP and TBHP. These registers define the total address of the look-up table.

After setting up the table pointer, the table data can be retrieved from the Program Memory using the “TABRD [m]” or “TABRDL [m]” instructions respectively. When the instruction is executed, the lower order table byte from the Program Memory will be transferred to the user defined Data Memory register [m] as specified in the instruction. The higher order table data byte from the Program Memory will be transferred to the TBLH special register. Any unused bits in this transferred higher order byte will be read as “0”.

---

HT45F56
Shock Detector Flash MCU

Page 15
November 26, 2019
The accompanying diagram illustrates the addressing data flow of the look-up table.

![Diagram](attachment:look-up_table_diagram.png)

Table Program Example

The accompanying example shows how the table pointer and table data is defined and retrieved from the device. This example uses raw table data located in the last page which is stored there using the ORG statement. The value at this ORG statement is “300H” which refers to the start address of the last page within the 1K Program Memory of the device. The table pointer low byte register is setup here to have an initial value of “06H”. This will ensure that the first data read from the data table will be at the Program Memory address “306H” or 6 locations after the start of the last page. Note that the value for the table pointer is referenced to the first address of the present page if the “TABRD [m]” instruction is being used. The high byte of the table data which in this case is equal to zero will be transferred to the TBLH register automatically when the “TABRD [m]” instruction is executed. Because the TBLH register is a read-only register and cannot be restored, care should be taken to ensure its protection if both the main routine and Interrupt Service Routine use table read instructions. If using the table read instructions, the Interrupt Service Routines may change the value of the TBLH and subsequently cause errors if used again by the main routine. As a rule it is recommended that simultaneous use of the table read instructions should be avoided. However, in situations where simultaneous use cannot be avoided, the interrupts should be disabled prior to the execution of any main routine table-read instructions. Note that all table related instructions require two instruction cycles to complete their operation.

Table Read Program Example

```assembly
tempreg1 db ?   ; temporary register #1
tempreg2 db ?   ; temporary register #2

mov a,06h    ; initialise low table pointer - note that this address is referenced
mov tblp,a   ; to the last page or current page

: tabrd tempreg1 ; transfers value in table referenced by table pointer data at program
                ; memory address “306H” transferred to tempreg1 and TBLH
dec tblp     ; reduce value of table pointer by one

: tabrd tempreg2 ; transfers value in table referenced by table pointer data at program
                ; memory address “305H” transferred to tempreg2 and TBLH in this
                ; example the data “1AH” is transferred to tempreg1 and data “0FH” to
                ; register tempreg2

org 300h      ; sets initial address of program memory
dc  00Ah, 00Bh, 00Ch, 00Dh, 00Eh, 00Fh, 01Ah, 01Bh
```

```
In Circuit Programming – ICP

The provision of Flash type Program Memory provides the user with a means of convenient and easy upgrades and modifications to their programs on the same device.

As an additional convenience, Holtek has provided a means of programming the microcontroller in-circuit using a 4-pin interface. This provides manufacturers with the possibility of manufacturing their circuit boards complete with a programmed or un-programmed microcontroller, and then programming or upgrading the program at a later stage. This enables product manufacturers to easily keep their manufactured products supplied with the latest program releases without removal and re-insertion of the device.

<table>

</tr>
</tbody>
</table>

The Program Memory and EEPROM data memory can be programmed serially in-circuit using this 4-wire interface. Data is downloaded and uploaded serially on a single pin with an additional line for the clock. Two additional lines are required for the power supply. The technical details regarding the in-circuit programming of the device are beyond the scope of this document and will be supplied in supplementary literature.

During the programming process, the user must take care of the ICPDA and ICPCK pins for data and clock programming purposes to ensure that no other outputs are connected to these two pins.

Note: * may be resistor or capacitor. The resistance of * must be greater than 1k or the capacitance of * must be less than 1nF.
On-Chip Debug Support – OCDS

There is an EV chip named HT45V56 which is used to emulate the real MCU device named HT45F56. The EV chip device also provides the “On-Chip Debug” function to debug the real MCU device during development process. The EV chip and real MCU devices, HT45V56 and HT45F56, are almost functional compatible except the “On-Chip Debug” function. Users can use the EV chip device to emulate the real MCU device behaviors by connecting the OCDSDA and OCDSCK pins to the Holtek HT-IDE development tools. The OCDSDA pin is the OCDS Data/Address input/output pin while the OCDSCK pin is the OCDS clock input pin. For more detailed OCDS information, refer to the corresponding document named “Holtek e-Link for 8-bit MCU OCDS User’s Guide”.

Data Memory

The Data Memory is an 8-bit wide RAM internal memory and is the location where temporary information is stored.

Structure

Divided into two types, the first of Data Memory is an area of RAM where special function registers are located. These registers have fixed locations and are necessary for correct operation of the device. Many of these registers can be read from and written to directly under program control, however, some remain protected from user manipulation. The second area of Data Memory is reserved for general purpose use. All locations within this area are read and write accessible under program control.

The overall Data Memory is subdivided into two banks. The Special Purpose Data Memory registers are accessible in all banks, with the exception of the EEC register at address 40H, which is only accessible in Bank 1. Switching between the different Data Memory banks is achieved by setting the Bank Pointer to the correct value. The start address of the Data Memory for all devices is the address 00H.
General Purpose Data Memory

All microcontroller programs require an area of read/write memory where temporary data can be stored and retrieved for use later. It is this area of RAM memory that is known as General Purpose Data Memory. This area of Data Memory is fully accessible by the user programing for both reading and writing operations. By using the bit operation instructions individual bits can be set or reset under program control giving the user a large range of flexibility for bit manipulation in the Data Memory.

Special Purpose Data Memory

This area of Data Memory is where registers, necessary for the correct operation of the microcontroller, are stored. Most of the registers are both readable and writeable but some are protected and are readable only, the details of which are located under the relevant Special Function Register section. Note that for locations that are unused, any read instruction to these addresses will return the value “00H”.

Special Purpose Data Memory Structure
Special Function Register Description

Most of the Special Function Register details will be described in the relevant functional section. However, several registers require a separate description in this section.

Indirect Addressing Registers – IAR0, IAR1

The Indirect Addressing Registers, IAR0 and IAR1, although having their locations in normal RAM register space, do not actually physically exist as normal registers. The method of indirect addressing for RAM data manipulation uses these Indirect Addressing Registers and Memory Pointers, in contrast to direct memory addressing, where the actual memory address is specified. Actions on the IAR0 and IAR1 registers will result in no actual read or write operation to these registers but rather to the memory location specified by their corresponding Memory Pointers, MP0 or MP1. Acting as a pair, IAR0 and MP0 can together access data only from Bank 0 while the IAR1 register together with MP1 register can access data from any Data Memory bank. As the Indirect Addressing Registers are not physically implemented, reading the Indirect Addressing Registers indirectly will return a result of “00H” and writing to the registers indirectly will result in no operation.

Memory Pointers – MP0, MP1

The Indirect Addressing Registers, IAR0 and IAR1, although having their locations in normal RAM register space, do not actually physically exist as normal registers. The method of indirect addressing for RAM data manipulation uses these Indirect Addressing Registers and Memory Pointers, in contrast to direct memory addressing, where the actual memory address is specified. Actions on the IAR0 and IAR1 registers will result in no actual read or write operation to these registers but rather to the memory location specified by their corresponding Memory Pointers, MP0 or MP1. Acting as a pair, IAR0 and MP0 can together access data from Bank 0 while the IAR1 and MP1 register pair can access data from any bank. As the Indirect Addressing Registers are not physically implemented, reading the Indirect Addressing Registers indirectly will return a result of “00H” and writing to the registers indirectly will result in no operation.

Indirect Addressing Program Example

- Example 1

```assembly
.data .section 'data'
adres1 db ?
adres2 db ?
adres3 db ?
adres4 db ?
block db ?
.code .section at 0 code
org 00h
start:
mov a,04h    ; setup size of block
mov block,a
mov a,offset adres1 ; Accumulator loaded with first RAM address
mov mp0,a ; setup memory pointer with first RAM address
loop:
  clr IAR0    ; clear the data at address defined by MP0
  inc mp0 ; increment memory pointer
  sdnz block ; check if last memory location has been cleared
jmp loop
continue:
```

The important point to note here is that in the example shown above, no reference is made to specific RAM addresses.
Bank Pointer – BP

The Data Memory is divided into two banks, Bank 0 and Bank 1. Selecting the required Data Memory area is achieved using the Bank Pointer, BP. The Bank Pointer bit 0 is used to select Data Memory Bank 0 or Bank 1.

The Data Memory initialised to Bank 0 after a reset except for a WDT time-out reset in the Power Down Mode in which case the Data Memory bank remains unaffected. It should be noted that the Special Function Data Memory is not affected by the bank selection, which means that the Special Function Registers can be accessed irrespective of the value of the Bank Pointer. Accessing data from Bank 1 must be implemented using the Indirect Addressing.

</tr>
</tbody>
</table>

Bit 7~1 Unimplemented, read as “0”

Bit 0  
DMBP0: Data Memory Bank Point bit 0  
0: Bank 0  
1: Bank 1

Accumulator – ACC

The Accumulator is central to the operation of any microcontroller and is closely related with operations carried out by the ALU. The Accumulator is the place where all intermediate results from the ALU are stored. Without the Accumulator it would be necessary to write the result of each calculation or logical operation such as addition, subtraction, shift, etc., to the Data Memory resulting in higher programming and timing overheads. Data transfer operations usually involve the temporary storage function of the Accumulator; for example, when transferring data between one user-defined register and another, it is necessary to do this by passing the data through the Accumulator as no direct transfer between two registers is permitted.

Program Counter Low Register – PCL

To provide additional program control functions, the low byte of the Program Counter is made accessible to programmers by locating it within the Special Purpose area of the Data Memory. By manipulating this register, direct jumps to other program locations are easily implemented. Loading a value directly into this PCL register will cause a jump to the specified Program Memory location, however, as the register is only 8-bit wide, only jumps within the current Program Memory page are permitted. When such operations are used, note that a dummy cycle will be inserted.

Look-up Table Registers – TBLP, TBLH

These three special function registers are used to control operation of the look-up table which is stored in the Program Memory. TBLP is the table pointer and indicates the location where the table data is located. Their value must be setup before any table read commands are executed. Their value can be changed, for example using the “INC” or “DEC” instructions, allowing for easy table data pointing and reading. TBLH is the location where the high order byte of the table data is stored after a table read data instruction has been executed. Note that the lower order table data byte is transferred to a user defined location.
Status Register – STATUS

This 8-bit register contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF), and watchdog time-out flag (TO). These arithmetic/logical operation and system management flags are used to record the status and operation of the microcontroller.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PDF flag. In addition, operations related to the status register may give different results due to the different instruction operations. The TO flag can be affected only by a system power-up, a WDT time-out or by executing the “CLR WDT” or “HALT” instruction. The PDF flag is affected only by executing the “HALT” or “CLR WDT” instruction or during a system power-up.

The Z, OV, AC and C flags generally reflect the status of the latest operations.

- **C** is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
- **AC** is set if an operation results in a carry out of the low nibbles in addition, or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
- **Z** is set if the result of an arithmetic or logical operation is zero; otherwise Z is cleared.
- **OV** is set if an operation results in a carry into the highest-order bit but not a carry out of the highest-order bit, or vice versa; otherwise OV is cleared.
- **PDF** is cleared by a system power-up or executing the “CLR WDT” instruction. PDF is set by executing the “HALT” instruction.
- **TO** is cleared by a system power-up or executing the “CLR WDT” or “HALT“ instruction. TO is set by a WDT time-out.

In addition, on entering an interrupt sequence or executing a subroutine call, the status register will not be pushed onto the stack automatically. If the contents of the status registers are important and if the subroutine can corrupt the status register, precautions must be taken to correctly save it.

- **Bit 1**: **AC**: Auxiliary flag
  - 0: No auxiliary carry
  - 1: An operation results in a carry out of the low nibbles, in addition, or no borrow from the high nibble into the low nibble in subtraction
- **Bit 0**: **C**: Carry flag
  - 0: No carry-out
  - 1: An operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation

The “C” flag is also affected by a rotate through carry instruction.
EEPROM Data Memory

These devices contain an area of internal EEPROM Data Memory. EEPROM, which stands for Electrically Erasable Programmable Read Only Memory, is by its nature a non-volatile form of re-programmable memory, with data retention even when its power supply is removed. By incorporating this kind of data memory, a whole new host of application possibilities are made available to the designer. The availability of EEPROM storage allows information such as product identification numbers, calibration values, specific user data, system setup data or other product information to be stored directly within the product microcontroller. The process of reading and writing data to the EEPROM memory has been reduced to a very trivial affair.

<table>
<thead>
<tr>
<th>Capacity</th>
<th>Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>32 x 8</td>
<td>00H ~ 1FH</td>
</tr>
</tbody>
</table>

EEPROM Data Memory Structure

The EEPROM Data Memory capacity is 32×8 bits for the device. Unlike the Program Memory and RAM Data Memory, the EEPROM Data Memory is not directly mapped into memory space and is therefore not directly addressable in the same way as the other types of memory. Read and Write operations to the EEPROM are carried out in single byte operations using an address and data register in Bank 0 and a single control register in Bank 1.

EEPROM Registers

Three registers control the overall operation of the internal EEPROM Data Memory. These are the address register, EEA, the data register, EED and a single control register, EEC. As both the EEA and EED registers are located in sector 0, they can be directly accessed in the same was as any other Special Function Register. The EEC register, however, being located in sector 1, can be read from or written to indirectly using the MP1 Memory Pointer and Indirect Addressing Register, IAR1. Because the EEC control register is located at address 40H in Bank 1, the Memory Pointer low byte register, MP1, must first be set to the value 40H and the Bank Pointer register, BP, set to the value, 01H, before any operations on the EEC register are executed.

Bit 7–4  Unimplemented, read as 0.

Bit 3  **WREN**: Data EEPROM write enable

0: Disable
1: Enable

This is the Data EEPROM Write Enable Bit which must be set high before Data EEPROM write operations are carried out. Clearing this bit to zero will inhibit Data EEPROM write operations.

Bit 2  **WR**: EEPROM write control

0: Write cycle has finished
1: Activate a write cycle

This is the Data EEPROM Write Control Bit and when set high by the application program will activate a write cycle. This bit will be automatically reset to zero by the hardware after the write cycle has finished. Setting this bit high will have no effect if the WREN has not first been set high.

Bit 1  **RDEN**: Data EEPROM read enable

0: Disable
1: Enable

This is the Data EEPROM Read Enable Bit which must be set high before Data EEPROM read operations are carried out. Clearing this bit to zero will inhibit Data EEPROM read operations.

Bit 0  **RD**: EEPROM read control

0: Read cycle has finished
1: Activate a read cycle

This is the Data EEPROM Read Control Bit and when set high by the application program will activate a read cycle. This bit will be automatically reset to zero by the hardware after the read cycle has finished. Setting this bit high will have no effect if the RDEN has not first been set high.

Note: The WREN, WR, RDEN and RD can not be set to “1” at the same time in one instruction. The WR and RD can not be set to “1” at the same time.
Reading Data from the EEPROM

To read data from the EEPROM, the read enable bit, RDEN, in the EEC register must first be set high to enable the read function. The EEPROM address of the data to be read must then be placed in the EEA register. If the RD bit in the EEC register is now set high, a read cycle will be initiated. Setting the RD bit high will not initiate a read operation if the RDEN bit has not been set. When the read cycle terminates, the RD bit will be automatically cleared to zero, after which the data can be read from the EED register. The data will remain in the EED register until another read or write operation is executed. The application program can poll the RD bit to determine when the data is valid for reading.

Writing Data to the EEPROM

To write data to the EEPROM, the EEPROM address of the data to be written must first be placed in the EEA register and the data placed in the EED register. Then the write enable bit, WREN, in the EEC register must first be set high to enable the write function. After this, the WR bit in the EEC register must be immediately set high to initiate a write cycle. These two instructions must be executed consecutively. The global interrupt bit EMI should also first be cleared before implementing any write operations, and then set again after the write cycle has started. Note that setting the WR bit high will not initiate a write cycle if the WREN bit has not been set. As the EEPROM write cycle is controlled using an internal timer whose operation is asynchronous to microcontroller system clock, a certain time will elapse before the data will have been written into the EEPROM. Detecting when the write cycle has finished can be implemented either by polling the WR bit in the EEC register or by using the EEPROM interrupt. When the write cycle terminates, the WR bit will be automatically cleared to zero by the microcontroller, informing the user that the data has been written to the EEPROM. The application program can therefore poll the WR bit to determine when the write cycle has ended.

Write Protection

Protection against inadvertent write operation is provided in several ways. After the device is powered on, the Write Enable bit in the control register will be cleared preventing any write operations. Also at power-on the Bank Pointer register, BP, will be reset to zero, which means that Data Memory Bank 0 will be selected. As the EEPROM control register is located in Bank 1, this adds a further measure of protection against spurious write operations. During normal program operation, ensuring that the Write Enable bit in the control register is cleared will safeguard against incorrect write operations.

EEPROM Interrupt

The EEPROM write interrupt is generated when an EEPROM write cycle has ended. The EEPROM interrupt must first be enabled by setting the DEE bit in the relevant interrupt register. When an EEPROM write cycle ends, the DEF request flag will be set. If the global, EEPROM interrupts are enabled and the stack is not full, a subroutine call to the EEPROM Interrupt vector will take place. When the interrupt is serviced, the EEPROM interrupt flag DEF will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.
Programming Considerations

Care must be taken that data is not inadvertently written to the EEPROM. Protection can be periodic by ensuring that the Write Enable bit is normally cleared to zero when not writing. Also the Bank Pointer could be normally cleared to zero as this would inhibit access to Bank 1 where the EEPROM control register exist. Although certainly not necessary, consideration might be given in the application program to the checking of the validity of new write data by a simple read back process. When writing data the WR bit must be set high immediately after the WREN bit has been set high, to ensure the write cycle executes correctly. The global interrupt bit EMI should also be cleared before a write cycle is executed and then re-enabled after the write cycle starts. Note that the device should not enter the IDLE or SLEEP mode until the EEPROM read or write operation is totally complete. Otherwise, the EEPROM read or write operation will fail.

Programming Example

• Reading data from the EEPROM – polling method

```assembly
MOV A, EEPROM_ADRES  ; user defined address
MOV EEA, A
MOV A, 040H  ; setup memory pointer MP1
MOV MP1, A  ; MP1 points to EEC register
MOV A, 01H  ; setup Bank Pointer BP
MOV BP, A
SET IAR1.1 ; set RDEN bit, enable read operations
SET IAR1.0 ; start Read Cycle - set RD bit
BACK:
SZ IAR1.0 ; check for read cycle end
JMP BACK
CLR IAR1 ; disable EEPROM write
CLR BP
MOV A, EED ; move read data to register
MOV READ_DATA, A
```

• Writing Data to the EEPROM – polling method

```assembly
MOV A, EEPROM_ADRES  ; user defined address
MOV EEA, A
MOV A, EEPROM_DATA  ; user defined data
MOV EED, A
MOV A, 040H  ; setup memory pointer MP1
MOV MP1, A  ; MP1 points to EEC register
MOV A, 01H  ; setup Bank Pointer BP
MOV BP, A
CLR EMI
SET IAR1.3 ; set WREN bit, enable write operations
SET IAR1.2 ; start Write Cycle - set WR bit
SET EMI
BACK:
SZ IAR1.2 ; check for write cycle end
JMP BACK
CLR IAR1 ; disable EEPROM write
CLR BP
```
Oscillator

Various oscillator types offer the user a wide range of functions according to their various application requirements. The flexible features of the oscillator functions ensure that the best optimisation can be achieved in terms of speed and power saving. Oscillator selections and operation are selected through a combination of application program and relevant control registers.

Oscillator Overview

In addition to being the source of the main system clock the oscillators also provide clock sources for the Watchdog Timer and Time Base Interrupts. External oscillators requiring some external components as well as fully integrated internal oscillators, requiring no external components, are provided to form a wide range of both fast and slow system oscillators. The higher frequency oscillator provides higher performance but carries with it the disadvantage of higher power requirements, while the opposite is of course true for the lower frequency oscillator. With the capability of dynamically switching between fast and slow system clock, the device has the flexibility to optimize the performance/power ratio, a feature especially important in power sensitive portable applications.

<table>

<td>HIRC</td>
<td>8 MHz</td>
</tr>
<tr>
<td>Internal Low Speed RC</td>
<td>LIRC</td>
<td>32 kHz</td>
</tr>
</tbody>
</table>

Oscillator Types

System Clock Configurations

There are two methods of generating the system clock, one high speed oscillator and one low speed oscillator. The high speed oscillator is the internal 8 MHz RC oscillator, HIRC. The low speed oscillator is the internal 32 kHz RC oscillator, LIRC. Selecting whether the low or high speed oscillator is used as the system oscillator is implemented using the HLCLK and CKS2~CKS0 bits in the SMOD register and as the system clock can be dynamically selected. Note that two oscillator selections must be made namely one high speed and one low speed system oscillators. It is not possible to choose a no-oscillator selection for either the high or low speed oscillator.
Internal High Speed RC Oscillator – HIRC

The internal RC oscillator is a fully integrated system oscillator requiring no external components. The internal RC oscillator has a fixed frequency of 8 MHz. Device trimming during the manufacturing process and the inclusion of internal frequency compensation circuits are used to ensure that the influence of the power supply voltage, temperature and process variations on the oscillation frequency are minimised. As a result, at a power supply of 5V and at a temperature of 25°C degrees, the fixed oscillation frequency of 8MHz will have a tolerance within 2%.

Internal 32kHz Oscillator – LIRC

The Internal 32 kHz System Oscillator is the low frequency oscillator choices and fully integrated with a typical frequency of 32 kHz at 5V, requiring no external components for its implementation. Device trimming during the manufacturing process and the inclusion of internal frequency compensation circuits are used to ensure that the influence of the power supply voltage, temperature and process variations on the oscillation frequency are minimised.

Supplementary Oscillators

The low speed oscillator, in addition to providing a system clock source is also used to provide a clock source to two other device functions. These are the Watchdog Timer and the Time Base Interrupts.

Operating Modes and System Clocks

Present day applications require that their microcontrollers have high performance but often still demand that they consume as little power as possible, conflicting requirements that are especially true in battery powered portable applications. The fast clocks required for high performance will by their nature increase current consumption and of course vice-versa, lower speed clocks reduce current consumption. As Holtek has provided these devices with both high and low speed clock sources and the means to switch between them dynamically, the user can optimise the operation of their microcontroller to achieve the best performance/power ratio.

System Clocks

The device has different clock sources for both the CPU and peripheral function operation. By providing the user with a wide range of clock selections using register programming, a clock system can be configured to obtain maximum application performance.

The main system clock can come from either a high frequency $f_H$ or low frequency $f_S$ source and is selected using the HLCLK and CKS2~CKS0 bits in the SMOD register. The high speed system clock is sourced from the HIRC oscillator while the low speed system clock source is sourced from the internal clock $f_S$. The other choice, which is a divided version of the high speed system oscillator has a range of $f_H/2$~$f_H/64$.

There is one additional internal clock for the peripheral circuits, the Time Base clock, $f_{TBC}$. The $f_{TBC}$ clock is sourced from the LIRC oscillator and used as a source for the Time Base interrupt functions and for the TM.
HT45F56
Shock Detector Flash MCU

Device Clock Configurations

Note: When the system clock source $f_{SYS}$ is switched to $f_{SUB}$ from $f_{H}$, the high speed oscillation can be stopped to conserve the power. Therefore, there is no $f_{H}$~$f_{H}/64$ clock source for peripheral circuit to use.

System Operation Modes

There are six different modes of operation for the microcontroller, each one with its own special characteristics and which can be chosen according to the specific performance and power requirements of the application. There are two modes allowing normal operation of the microcontroller, the NORMAL Mode and SLOW Mode. The remaining four modes, the SLEEP0, SLEEP1, IDLE0 and IDLE1 Modes are used when the microcontroller CPU is switched off to conserve power.

<td>Off</td>
<td>On</td>
<td>Off</td>
</tr>
</tbody>
</table>

NORMAL Mode

As the name suggests this is one of the main operating modes where the microcontroller has all of its functions operational and where the system clock is provided by the high speed oscillators. This mode operates allowing the microcontroller to operate normally with a clock source will come from the high speed oscillators, HIRC. The high speed oscillator will however first be divided by a ratio ranging from 1 to 64, the actual ratio being selected by the CKS2–CKS0 and HLCLK bits in the SMOD register. Although a high speed oscillator is used, running the microcontroller at a divided clock ratio reduces the operating current.
SLOW Mode
This is also a mode where the microcontroller operates normally although now with a slower speed clock source. The clock source used will be from \( f_{\text{SUB}} \). The \( f_{\text{SUB}} \) clock is derived from the LIRC oscillator. Running the microcontroller in this mode allows it to run with much lower operating currents. In the SLOW mode, the \( f_o \) is switched off.

SLEEP0 Mode
The SLEEP0 Mode is entered when an HALT instruction is executed and when the IDLEN bit is low. In the SLEEP0 mode the CPU will be stopped and the \( f_{\text{SUB}} \) clock will also be stopped as the Watchdog Timer function is disabled.

SLEEP1 Mode
The SLEEP1 Mode is entered when an HALT instruction is executed and when the IDLEN bit is low. In the SLEEP1 mode the CPU will be stopped. However, the \( f_{\text{SUB}} \) clock will continue to run as the Watchdog Timer function is enabled.

IDLE0 Mode
The IDLE0 Mode is entered when an HALT instruction is executed and when the IDLEN bit is high and the FSYS0N bit is low. In the IDLE0 Mode the system oscillator will be inhibited from driving the CPU but some peripheral functions will remain operational such as the Watchdog Timer and TMs. In the IDLE0 mode, the system oscillator will be stopped.

IDLE1 Mode
The IDLE1 Mode is entered when an HALT instruction is executed and when the IDLEN bit is high and the FSYS0N bit is high. In the IDLE1 Mode the system oscillator will be inhibited from driving the CPU but may continue to provide a clock source to keep some peripheral functions operational such as the Watchdog Timer and TMs. In the IDLE1 mode, the system oscillator will continue to run and this system oscillator may be high or low speed system oscillator. In IELD1 mode, the Watchdog Timer clock, \( f_{\text{SUB}} \), will be switched on.

Control Registers
The register, SMOD, is used for overall control of the internal clocks within the device.

Bit 7~5  | CKS2~CKS0: System clock selection
000: \( f_{\text{SUB}} \)
001: \( f_{\text{SUB}} \)
010: \( f_o/64 \)
011: \( f_o/32 \)
100: \( f_o/16 \)
101: \( f_o/8 \)
110: \( f_o/4 \)
111: \( f_o/2 \)

These three bits are used to select which clock is used as the system clock source. In addition to the system clock source, which can be the \( f_{\text{SUB}} \) clock source, a divided version of the high speed system oscillator can also be chosen as the system clock source.
Bit 4  Unimplemented, read as 0.

Bit 3  **LTO**: Low speed system oscillator ready flag
       0: Not ready
       1: Ready

This is the low speed system oscillator ready flag which indicates when the low speed
system oscillator is stable after power on reset or a wake-up has occurred. The flag
will be low when in the SLEEP0 mode, but after a wake-up has occurred the flag will
change to a high level after 1~2 cycles as the LIRC oscillator is used.

Bit 2  **HTO**: High speed system oscillator ready flag
       0: Not ready
       1: Ready

This is the high speed system oscillator ready flag which indicates when the high speed
system oscillator is stable. This flag is cleared to “0” by hardware when the device is
powered on and then changes to a high level after the high speed system oscillator is
stable. Therefore this flag will always be read as “1” by the application program after
device power-on.

Bit 1  **IDLEN**: IDLE mode control
       0: Disable
       1: Enable

This is the IDLE mode control bit and determines what happens when the HALT
instruction is executed. If this bit is high, when a HALT instruction is executed the
device will enter the IDLE Mode. In the IDLE1 Mode, the CPU will stop running
but the system clock will continue to keep the peripheral functions operational, as the
FSYSON bit is high. If the FSYSON bit is low, the CPU and the system clock will all
stop in the IDLE0 mode. If this bit is low, the device will enter the SLEEP Mode when
a HALT instruction is executed.

Bit 0  **HLCLK**: System clock selection
       0: \( f_H / 2 \sim f_H / 64 \) or \( f_{SUB} \)
       1: \( f_H \)

This bit is used to select if the \( f_H \) clock, the \( f_H / 2 \sim f_H / 64 \) clock or the \( f_{SUB} \) clock is used
as the system clock. When this bit is high, the \( f_H \) clock will be selected and if low the
\( f_H / 2 \sim f_H / 64 \) or \( f_{SUB} \) clock will be selected. When the system clock switches from the \( f_H \) clock to the \( f_{SUB} \) clock and the \( f_H \) clock will be automatically switched off to conserve
power.

Bit 0  **WRF**: WDT control register software reset flag
Described elsewhere.
Operating Mode Switching

The devices can switch between operating modes dynamically allowing the user to select the best performance/power ratio for the present task in hand. In this way microcontroller operations that do not require high performance can be executed using slower clocks thus requiring less operating current and prolonging battery life in portable applications. In simple terms, Mode Switching between the NORMAL Mode and SLOW Mode is executed using the HLCLK bit and CKS2~CKS0 bits in the SMOD register while Mode Switching from the NORMAL/ SLOW Modes to the SLEEP/ IDLE Modes is executed via the HALT instruction. When a HALT instruction is executed, whether the device enters the IDLE Mode or the SLEEP Mode is determined by the condition of the IDLEN bit in the SMOD register and FSYSON in the SMOD1 register. When the HLCLK bit switches to a low level, which implies that clock source is switched from the high speed clock source, fH, to the clock source, fSUB/2~ fSUB/64 or fSUB. If the clock is from the fSUB, the high speed clock source will stop running to conserve power. When this happens it must be noted that the fH/16 and fH/64 internal clock sources will also stop running, which may affect the operation of other internal functions such as the TMs.
NORMAL Mode to SLOW Mode Switching

When running in the NORMAL Mode, which uses the high speed system oscillator, and therefore consumes more power, the system clock can switch to run in the SLOW Mode by setting the HLCLK bit to “0” and setting the CKS2–CKS0 bits to “000” or “001” in the SMOD register. This will then use the low speed system oscillator which will consume less power. Users may decide to do this for certain operations which do not require high performance and can subsequently reduce power consumption.

The SLOW Mode is sourced from the LIRC oscillator and therefore requires this oscillator to be stable before full mode switching occurs. This is monitored using the LTO bit in the SMOD register.
SLOW Mode to NORMAL Mode Switching

In SLOW mode the system clock is derived from f_{SUB}. To switch back to the NORMAL Mode, where the high speed system oscillator is used, the HLCLK bit should be set to “1” or HLCLK bit is “0” but the CKS2~CKS0 field is set to “01x” or “1xx”. As a certain amount of time will be required for the high frequency clock to stabilise, the status of the HTO bit is checked.

![Mode Switching Diagram]

Entering the SLEEP0 Mode

There is only one way for the device to enter the SLEEP0 Mode and that is to execute the “HALT” instruction in the application program with the IDLEN bit in the SMOD register equal to “0” and the WDT is off. When this instruction is executed under the conditions described above, the following will occur:

- The system clock, WDT clock and Time Base clock will be stopped and the application program will stop at the "HALT" instruction.
- The Data Memory contents and registers will maintain their present condition.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag PDF will be set, and WDT timeout flag TO will be cleared.
- The WDT will be cleared and stopped as the WDT is disabled.
Entering the SLEEP1 Mode

There is only one way for the device to enter the SLEEP1 Mode and that is to execute the “HALT” instruction in the application program with the IDLEN bit in the SMOD register equal to “0” and the WDT is on. When this instruction is executed under the conditions described above, the following will occur:

- The system clock and Time Base clock will be stopped and the application program will stop at the "HALT" instruction. However, the WDT clock will continue to run.
- The Data Memory contents and registers will maintain their present condition.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag PDF will be set, and WDT timeout flag TO will be cleared.
- The WDT will be cleared and resume counting as the WDT is enabled.

Entering the IDLE0 Mode

There is only one way for the device to enter the IDLE0 Mode and that is to execute the “HALT” instruction in the application program with the IDLEN bit in the SMODE register equal to “1” and the FSYSON bit in the SMOD1 register equal to “0”. When this instruction is executed under the conditions described above, the following will occur:

- The system clock will be stopped and the application program will stop at the “HALT” instruction, but the Time Base clock will be on.
- The Data Memory contents and registers will maintain their present condition.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag PDF will be set, and WDT timeout flag TO will be cleared.
- The WDT will be cleared and resume counting if the WDT function is enabled.

Entering the IDLE1 Mode

There is only one way for the device to enter the IDLE1 Mode and that is to execute the “HALT” instruction in the application program with IDLEN bit in the SMODE register equal to “1” and the FSYSON bit in the SMOD1 register equal to “1”. When this instruction is executed under the conditions described above, the following will occur:

- The system clock and Time Base clock will be on but the application program will stop at the “HALT” instruction.
- The Data Memory contents and registers will maintain their present condition.
- The I/O ports will maintain their present conditions.
- In the status register, the Power Down flag PDF will be set, and WDT timeout flag TO will be cleared.
- The WDT will be cleared and resume counting if the WDT function is enabled.
Standby Current Considerations

As the main reason for entering the SLEEP or IDLE Mode is to keep the current consumption of the device to as low a value as possible, perhaps only in the order of several micro-amps except in the IDLE1 Mode, there are other considerations which must also be taken into account by the circuit designer if the power consumption is to be minimised. Special attention must be made to the I/O pins on the device. All high-impedance input pins must be connected to either a fixed high or low level as any floating input pins could create internal oscillations and result in increased current consumption. This also applies to devices which have different package types, as there may be unbonbed pins. These must either be setup as outputs or if setup as inputs must have pull-high resistors connected.

Care must also be taken with the loads, which are connected to I/O pins, which are setup as outputs. These should be placed in a condition in which minimum current is drawn or connected only to external circuits that do not draw current, such as other CMOS inputs. In the IDLE1 Mode the system oscillator is on, if the peripheral function clock source is derived from the high speed system oscillator, the additional standby current will also be perhaps in the order of several hundred micro-amps.

Wake-up

To minimise power consumption the device can enter the SLEEP or any IDLE Mode, where the CPU will be switched off. However, when the device is woken up again, it will take a considerable time for the original system oscillator to restart, stabilise and allow normal operation to resume.

After the system enters the SLEEP or IDLE Mode, it can be woken up from one of various sources listed as follows:

- An external reset
- An external falling edge on Port A
- A system interrupt
- A WDT overflow

If the system is woken up by an external reset, the device will experience a full system reset. However, if the device is woken up by a WDT overflow, a Watchdog Timer reset will be initiated. Although both of these wake-up methods will initiate a reset operation, the actual source of the wake-up can be determined by examining the TO and PDF flags. The PDF flag is cleared by a system power-up or executing the clear Watchdog Timer instructions and is set when executing the “HALT” instruction. The TO flag is set if a WDT time-out occurs, and causes a wake-up that only resets the Program Counter and Stack Pointer, the other flags remain in their original status.

Each pin on Port A can be setup using the PAWU register to permit a negative transition on the pin to wake up the system. When a Port A pin wake-up occurs, the program will resume execution at the instruction following the “HALT” instruction. If the system is woken up by an interrupt, then two possible situations may occur. The first is where the related interrupt is disabled or the interrupt is enabled but the stack is full, in which case the program will resume execution at the instruction following the “HALT” instruction. In this situation, the interrupt which woke up the device will not be immediately serviced, but will rather be serviced later when the related interrupt is finally enabled or when a stack level becomes free. The other situation is where the related interrupt is enabled and the stack is not full, in which case the regular interrupt response takes place. If an interrupt request flag is set high before entering the SLEEP or IDLE Mode, the wake-up function of the related interrupt will be disabled.
Watchdog Timer

The Watchdog Timer is provided to prevent program malfunctions or sequences from jumping to unknown locations, due to certain uncontrollable external events such as electrical noise.

Watchdog Timer Clock Source

The Watchdog Timer clock source is provided by the internal $f_{\text{sub}}$ clock derived from the LIRC oscillator. The LIRC internal oscillator has an approximate frequency of 32 kHz and this specified internal clock period can vary with $V_{\text{DD}}$, temperature and process variations. The Watchdog Timer source clock is then subdivided by a ratio of $2^8$ to $2^{15}$ to give longer timeouts, the actual value being chosen using the WS2~WS0 bits in the WDTC register.

Watchdog Timer Control Register

A single register, WDTC, controls the required timeout period as well as the enable/disable operation. This register controls the overall operation of the Watchdog Timer. The WRF software reset flag is used to indicate whether the WDT control register software reset occurs or not.

WDTC Register

Bit 7–3  **WE4–WE0**: WDT function enable control
- 10101: Disabled
- 01010: Enabled
- Other values: Reset MCU

If these bits are changed due to adverse environmental conditions, the microcontroller will be reset. The reset operation will be activated after 2~3 LIRC clock cycles and the WRF bit in the SMOD1 register will be set to 1.

Bit 2–0  **WS2–WS0**: WDT time-out period selection
- 000: $2^8/f_{\text{sub}}$
- 001: $2^9/f_{\text{sub}}$
- 010: $2^{10}/f_{\text{sub}}$
- 011: $2^{11}/f_{\text{sub}}$
- 100: $2^{12}/f_{\text{sub}}$
- 101: $2^{13}/f_{\text{sub}}$
- 110: $2^{14}/f_{\text{sub}}$
- 111: $2^{15}/f_{\text{sub}}$

These three bits determine the division ratio of the watchdog timer source clock, which in turn determines the time-out period.

"x": unknown

Bit 7  **FSYSON**: f_{SYS} control in IDLE mode
Described elsewhere.

Bit 6–4  Unimplemented, read as “0”

Bit 3  **RSTF**: Reset control register software reset flag
Described elsewhere.

Bit 2  **LVRF**: LVR function reset flag
Described elsewhere.

Bit 1  Unimplemented, read as “0”

Bit 0  **WRF**: WDT control register software reset flag

0: Not occurred
1: Occurred

This bit is set to 1 by the WDT control register software reset and cleared by the application program. Note that this bit can only be cleared to 0 by the application program.

**Watchdog Timer Operation**

The Watchdog Timer operates by providing a device reset when its timer overflows. This means that in the application program and during normal operation the user has to strategically clear the Watchdog Timer before it overflows to prevent the Watchdog Timer from executing a reset. This is done using the clear watchdog instruction. If the program malfunctions for whatever reason, jumps to an unknown location, or enters an endless loop, the clear instruction will not be executed in the correct manner, in which case the Watchdog Timer will overflow and reset the device. With regard to the Watchdog Timer enable/disable function, there are five bits, WE4~WE0, in the WDTC register to offer the enable/disable control and reset control of the Watchdog Timer. The WDT function will be disabled when the WE4~WE0 bits are set to a value of 10101B while the WDT function will be enabled if the WE4~WE0 bits are equal to 01010B. If the WE4~WE0 bits are set to any other values, other than 01010B and 10101B, it will reset the device after 2~3 f_{LIRC} clock cycles. After power on these bits will have a value of 01010B.

</tbody>
</table>

**Watchdog Timer Enable/Disable Control**

Under normal program operation, a Watchdog Timer time-out will initialise a device reset and set the status bit TO. However, if the system is in the SLEEP or IDLE Mode, when a Watchdog Timer time-out occurs, the TO bit in the status register will be set and only the Program Counter and Stack Pointer will be reset. Four methods can be adopted to clear the contents of the Watchdog Timer. The first is a WDT reset, which means a certain value except 01010B and 10101B written into the WE4~WE0 field, the second is using the Watchdog Timer software clear instruction, the third is using a HALT instruction and the fourth is an external hardware reset.

There is only one method of using software instruction to clear the Watchdog Timer. That is to use the single “CLR WDT” instruction to clear the WDT contents.
The maximum time out period is when the $2^{15}$ division ratio is selected. As an example, with a 32 kHz LIRC oscillator as its source clock, this will give a maximum watchdog period of around 1 second for the $2^{15}$ division ratio and a minimum timeout of 7.8ms for the $2^8$ division ratio.

**Reset and Initialisation**

A reset function is a fundamental part of any microcontroller ensuring that the devices can be set to some predetermined condition irrespective of outside parameters. The most important reset condition is after power is first applied to the microcontroller. In this case, internal circuitry will ensure that the microcontroller, after a short delay, will be in a well defined state and ready to execute the first program instruction. After this power-on reset, certain important internal registers will be set to defined states before the program commences. One of these registers is the Program Counter, which will be reset to zero forcing the microcontroller to begin program execution from the lowest Program Memory address.

In addition to the power-on reset, situations may arise where it is necessary to forcefully apply a reset condition when the microcontroller is running. One example of this is where after power has been applied and the microcontroller is already running, the RES line is forcefully pulled low. In such a case, known as a normal operation reset, some of the microcontroller registers remain unchanged allowing the microcontroller to proceed with normal operation after the reset line is allowed to return high.

Another type of reset is when the Watchdog Timer overflows and resets the microcontroller. All types of reset operations result in different register conditions being setup. Another reset exists in the form of a Low Voltage Reset, LVR, where a full reset is implemented in situations where the power supply voltage falls below a certain threshold.

**Reset Functions**

There are five ways in which a microcontroller reset can occur, through events occurring both internally and externally.
**Power-on Reset**

The most fundamental and unavoidable reset is the one that occurs after power is first applied to the microcontroller. As well as ensuring that the Program Memory begins execution from the first memory address, a power-on reset also ensures that certain other registers are preset to known conditions. All the I/O port and port control registers will power up in a high condition ensuring that all pins will be first set to inputs.

Note: $t_{RSTD}$ is power-on delay with typical time = 50 ms

#### Power-On Reset Timing Chart

**RES Pin Reset**

Although the microcontroller has an internal RC reset function, if the $V_{DD}$ power supply rise time is not fast enough or does not stabilise quickly at power-on, the internal reset function may be incapable of providing proper reset operation. For this reason it is recommended that an external RC network is connected to the RES pin, whose additional time delay will ensure that the RES pin remains low for an extended period to allow the power supply to stabilise. During this time delay, normal operation of the microcontroller will be inhibited. After the RES line reaches a certain voltage value, the reset delay time $t_{RSTD}$ is invoked to provide an extra delay time after which the microcontroller will begin normal operation. The abbreviation SST in the figures stands for System Start-up Timer.

For most applications a resistor connected between $V_{DD}$ and the RES pin and a capacitor connected between VSS and the RES pin will provide a suitable external reset circuit. Any wiring connected to the RES pin should be kept as short as possible to minimize any stray noise interference. For applications that operate within an environment where more noise is present the Enhanced Reset Circuit shown is recommended.

More information regarding external reset circuits is located in Application Note HA0075E on the Holtek website.

```
VDD
1N4148*
10kO~100kO
0.01µF*
0.1µF~1µF
300O*
RES
VSS
```

Note: "***" It is recommended that this component is added for added ESD protection.

"****" It is recommended that this component is added in environments where power line noise is significant.
Pulling the `RES` Pin low using external hardware will also execute a device reset. In this case, as in the case of other resets, the Program Counter will reset to zero and program execution initiated from this point.

![Internal Reset Diagram]

Note: $t_{RSTD}$ is power-on delay with typical time = 16.7 ms

**RES Reset Timing Chart**

There is an internal reset control register, RSTC, which is used to provide a reset when the device operates abnormally due to the environmental noise interference. If the content of the RSTC register is set to any value other than 01010101B or 10101010B, it will reset the device after 2–3 LIRC clock cycles. After power on the register will have a value of 01010101B.

Described elsewhere.

**Low Voltage Reset – LVR**

The microcontroller contains a low voltage reset circuit in order to monitor the supply voltage of the device. The LVR function is always enabled with a specific LVR voltage, $V_{LVR}$. If the supply voltage of the device drops to within a range of $0.9V$–$V_{LVR}$ such as might occur when changing the battery, the LVR will automatically reset the device internally and the LVR bit in the SMOD1 register will also be set to 1. For a valid LVR signal, a low supply voltage, i.e., a voltage in the range between $0.9V$–$V_{LVR}$ must exist for a time greater than that specified by $t_{LVR}$ in the LVR characteristics. If the low supply voltage state does not exceed this value, the LVR will ignore the low supply voltage and will not perform a reset function. The actual $V_{LVR}$ value is 2.1V and the LVR circuit will reset the device when the supply voltage is less than 2.1V for more than the $t_{LVR}$ time. Note that the LVR function will be automatically disabled when the device enters the power down mode.

Described elsewhere.

Bit 6–4 Unimplemented, read as “0”

Bit 3  **RSTF**: Reset control register software reset flag
Described elsewhere.

Bit 2  **LVRF**: LVR function reset flag
0: Not occurred
1: Occurred
This bit is set to 1 when a specific low voltage reset condition occurs. Note that this bit can only be cleared to 0 by the application program.

Bit 1 Unimplemented, read as “0”

Bit 0  **WRF**: WDT control register software reset flag
Described elsewhere.

**Watchdog Time-out Reset during Normal Operation**

The Watchdog time-out Reset during normal operation is the same as the hardware Low Voltage Reset except that the Watchdog time-out flag TO will be set to “1”.

![Watchdog Time-out Reset during Normal Operation Diagram]

Note: t\textsubscript{RSTD} is power-on delay with typical time = 16.7 ms

**WDT Time-out Reset during NORMAL Operation Timing Chart**

**Watchdog Time-out Reset during SLEEP or IDLE Mode**

The Watchdog time-out Reset during SLEEP or IDLE Mode is a little different from other kinds of reset. Most of the conditions remain unchanged except that the Program Counter and the Stack Pointer will be cleared to “0” and the TO flag will be set to “1”. Refer to the A.C. Characteristics for t\textsubscript{SST} details.

![Watchdog Time-out Reset during SLEEP or IDLE Mode Diagram]

**WDT Time-out Reset during SLEEP or IDLE Mode Timing Chart**
Reset Initial Conditions

The different types of reset described affect the reset flags in different ways. These flags, known as PDF and TO are located in the status register and are controlled by various microcontroller operations, such as the SLEEP or IDLE Mode function or Watchdog Timer. The reset flags are shown in the table:

<table>
<thead>
<tr>

Input/Output Ports

Holtek microcontrollers offer considerable flexibility on their I/O ports. With the input or output designation of every pin fully under user program control, pull-high selections for all ports and wake-up selections on certain pins, the user is provided with an I/O structure to meet the needs of a wide range of application possibilities.

The device provides bidirectional input/output lines labeled with port name PA. These I/O ports are mapped to the RAM Data Memory with specific addresses as shown in the Special Purpose Data Memory table. All of these I/O ports can be used for input and output operations. For input operation, these ports are non-latching, which means the inputs must be ready at the T2 rising edge of instruction “MOV A, [m]”, where m denotes the port address. For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

1: Enable

PAWU\textsubscript{n}: Port A Pin wake-up function control

0: Disable
1: Enable

Pull-high Resistors

Many product applications require pull-high resistors for their switch inputs usually requiring the use of an external resistor. To eliminate the need for these external resistors, all I/O pins, when configured as an input have the capability of being connected to an internal pull-high resistor. These pull-high resistors are selected using the relevant pull-high control registers and are implemented using weak PMOS transistors.
**Port A Wake-up**

The HALT instruction forces the microcontroller into the SLEEP or IDLE Mode which preserves power, a feature that is important for battery and other low-power applications. Various methods exist to wake-up the microcontroller, one of which is to change the logic condition on one of the Port A pins from high to low. This function is especially suitable for applications that can be woken up via external switches. Each pin on Port A can be selected individually to have this wake-up feature using the PAWU register.

**I/O Port Control Register**

Each Port has its own control register, known as PAC, which controls the input/output configuration. With this control register, each I/O pin with or without pull-high resistors can be reconfigured dynamically under software control. For the I/O pin to function as an input, the corresponding bit of the control register must be written as a “1”. This will then allow the logic state of the input pin to be directly read by instructions. When the corresponding bit of the control register is written as a “0”, the I/O pin will be setup as a CMOS output. If the pin is currently setup as an output, instructions can still be used to read the output register.

However, it should be noted that the program will in fact only read the status of the output data latch and not the actual logic status of the output pin.

**Pin-shared Functions**

The flexibility of the microcontroller range is greatly enhanced by the use of pins that have more than one function. Limited numbers of pins can force serious design constraints on designers but by supplying pins with multi-functions, many of these difficulties can be overcome. For these pins, the desired function of the multi-function I/O pins is selected by a register via the application program control.

**Pin-shared Function Selection Registers**

The limited number of supplied pins in a package can impose restrictions on the amount of functions a certain device can contain. However by allowing the same pins to share several different functions and providing a means of function selection, a wide range of different functions can be incorporated into even relatively small package sizes. This device includes pin-shared function selection register, labeled as PSEL, which can select the desired functions of the multi-function pin-shared pins.

The most important point to note is to make sure that the desired pin-shared function is properly selected and also deselected. To select the desired pin-shared function, the pin-shared function should first be correctly selected using the corresponding pin-shared control register. After that the corresponding peripheral functional setting should be configured and then the peripheral function can be enabled. To correctly deselect the pin-shared function, the peripheral function should first be disabled and then the corresponding pin-shared function control register can be modified to select other pin-shared functions.

**I/O Pin Structures**

The accompanying diagrams illustrate the internal structures of some generic I/O pin types. As the exact logical construction of the I/O pin will differ from these drawings, they are supplied as a guide only to assist with the functional understanding of the I/O pins. The wide range of pin-shared structures does not permit all types to be shown.
Programming Considerations

Within the user program, one of the things first to consider is port initialisation. After a reset, all of the I/O data and port control registers will be set to high. This means that all I/O pins will be defaulted to an input state, the level of which depends on the other connected circuitry and whether pull-high selections have been chosen. If the port control registers are then programmed to setup some pins as outputs, these output pins will have an initial high output value unless the associated port data registers are first programmed. Selecting which pins are inputs and which are outputs can be achieved byte-wide by loading the correct values into the appropriate port control register or by programming individual bits in the port control register using the “SET [m].i” and “CLR [m].i” instructions. Note that when using these bit control instructions, a read-modify-write operation takes place. The microcontroller must first read in the data on the entire port, modify it to the required new bit values and then rewrite this data back to the output ports.

Port A has the additional capability of providing wake-up functions. When the device is in the SLEEP or IDLE Mode, various methods are available to wake the device up. One of these is a high to low transition of any of the Port A pins. Single or multiple pins on Port A can be setup to have this function.
Compact Type Timer Module – CTM

One of the most fundamental functions in any microcontroller devices is the ability to control and measure time. To implement time related functions the device includes one Timer Module, generally abbreviated to the name TM. This TM is the simplest type of the TMs which contains a multi-purpose timing unit. Although the simplest form of the TM types, the Compact TM type still contains three operating modes, which are Compare Match Output, Timer/Event Counter and PWM Output modes. The Compact TM can also be controlled with an external input pin and can drive one external output pin.

The key to understanding how the TM operates is to see it in terms of a free running count-up counter whose value is then compared with the value of pre-programmed internal comparators. When the free running count-up counter has the same value as the pre-programmed comparator, known as a compare match situation, a TM interrupt signal will be generated which can clear the counter and perhaps also change the condition of the TM output pin. The CTM has two interrupts, one for each of the internal comparator A or comparator P, which generate a TM interrupt when a compare match condition occurs. When a TM interrupt is generated, it can be used to clear the counter and also to change the state of the TM output pin.

The internal TM counter is driven by a user selectable clock source, which can be an internal clock or an external pin. The selection of the required clock source is implemented using the CTCK2~CTCK0 bits in the CTM control registers. The clock source can be a ratio of the system clock, fSYS, or the internal high clock, fH, the fSUB clock source or the external CTCK pin. The CTCK pin clock source is used to allow an external signal to drive the TM as an external clock source for event counting.

The TM output pin can be selected using the corresponding pin-shared function selection bits described in the Pin-shared Function section. When the TM is in the Compare Match Output Mode, these pins can be controlled by the TM to switch to a high or low level or to toggle when a compare match situation occurs. The external CTP output pin is also the pin where the TM generates the PWM output waveform. As the TM output pins are pin-shared with other functions, the TM output function must first be setup using relevant pin-shared function selection register.

Compact Type TM Block Diagram
Compact TM Operation

The Compact TM core is a 10-bit count-up counter which is driven by a user selectable internal or external clock source. There are also two internal comparators with the names, Comparator A and Comparator P. These comparators will compare the value in the counter with CCRP and CCRA registers. The CCRP is three-bit wide whose value is compared with the highest three bits in the counter while the CCRA is ten-bit wide and therefore compares with all counter bits.

The only way of changing the value of the 10-bit counter using the application program, is to clear the counter by changing the CTON bit from low to high. The counter will also be cleared automatically by a counter overflow or a compare match with one of its associated comparators. When these conditions occur, a TM interrupt signal will also usually be generated. The Compact Type TM can operate in a number of different operational modes, can be driven by different clock sources including an input pin and can also control an output pin. All operating setup conditions are selected using relevant internal registers.

Compact Type TM Register Description

Overall operation of the Compact TM is controlled using a series of registers. A read only register pair exists to store the internal counter 16-bit value, while a read/write register pair exists to store the internal 10-bit CCRA value. The remaining two registers are control registers which setup the different operating and control modes and as well as the three CCRP bits.

Bit 7 **CTPAU**: CTM Counter Pause control
- 0: Run
- 1: Pause
The counter can be paused by setting this bit high. Clearing the bit to zero restores normal counter operation. When in a Pause condition the CTM will remain powered up and continue to consume power. The counter will retain its residual value when this bit changes from low to high and resume counting from this value when the bit changes to a low value again.

Bit 6~4 **CTCK2~CTCK0**: Select CTM Counter clock
- 000: $f_{SYS}/4$
- 001: $f_{SYS}$
- 010: $f_{sub}/16$
- 011: $f_{sub}/64$
- 100: $f_{SUB}$
- 101: $f_{SUB}$
- 110: CTCK rising edge clock
- 111: CTCK falling edge clock
These three bits are used to select the clock source for the CTM. The external pin clock source can be chosen to be active on the rising or falling edge. The clock source $f_{SYS}$ is the system clock, while $f_{sub}$ are other internal clocks, the details of which can be found in the oscillator section.

Bit 3 **CTON**: CTM Counter On/Off control
- 0: Off
- 1: On
This bit controls the overall on/off function of the CTM. Setting the bit high enables the counter to run while clearing the bit disables the CTM. Clearing this bit to zero will stop the counter from counting and turn off the CTM which will reduce its power consumption. When the bit changes state from low to high the internal counter value will be reset to zero, however when the bit changes from high to low, the internal counter will retain its residual value until the bit returns high again. If the CTM is in the Compare Match Output Mode then the CTM output pin will be reset to its initial condition, as specified by the CTOC bit, when the CTON bit changes from low to high.
Bit 2–0  **CTRP2–CTRP0**: CTM CCRP 3-bit register, compared with the CTM Counter bit 9 – bit 7
000: 1024 CTM clocks
001: 128 CTM clocks
010: 256 CTM clocks
011: 384 CTM clocks
100: 512 CTM clocks
101: 640 CTM clocks
110: 768 CTM clocks
111: 896 CTM clocks

These three bits are used to setup the value on the internal CCRP 3-bit register, which are then compared with the internal counter’s highest three bits. The result of this comparison can be selected to clear the internal counter if the CTCCLR bit is set to zero. Setting the CTCCLR bit to zero ensures that a compare match with the CCRP values will reset the internal counter. As the CCRP bits are only compared with the highest three counter bits, the compare values exist in 128 clock cycle multiples. Clearing all three bits to zero is in effect allowing the counter to overflow at its maximum value.

</tbody>
</table>

**Bit 7–6  CTM1–CTM0**: Select CTM Operating Mode
00: Compare Match Output Mode
01: Undefined
10: PWM Mode
11: Timer/Counter Mode

These bits setup the required operating mode for the CTM. To ensure reliable operation the CTM should be switched off before any changes are made to the CTM1 and CTM0 bits. In the Timer/Counter Mode, the CTM output pin control will be disabled.

**Bit 5–4  CTIO1–CTIO0**: Select CTM external pin (CTP) function

**Compare Match Output Mode**
00: No change
01: Output low
10: Output high
11: Toggle output

**PWM Output Mode**
00: PWM output inactive state
01: PWM output active state
10: PWM output
11: Undefined

**Timer/Counter Mode**
Unused

These two bits are used to determine how the CTM output pin changes state when a certain condition is reached. The function that these bits select depends upon in which mode the CTM is running.
In the Compare Match Output Mode, the CTIO1 and CTIO0 bits determine how the CTM output pin changes state when a compare match occurs from the Comparator A. The CTM output pin can be setup to switch high, switch low or to toggle its present state when a compare match occurs from the Comparator A. When the bits are both zero, then no change will take place on the output. The initial value of the CTM output pin should be setup using the CTOC bit in the CTMC1 register. Note that the output level requested by the CTIO1 and CTIO0 bits must be different from the initial value setup using the CTOC bit otherwise no change will occur on the CTM output pin when a compare match occurs. After the CTM output pin changes state, it can be reset to its initial level by changing the level of the CTON bit from low to high.

In the PWM Mode, the CTIO1 and CTIO0 bits determine how the CTM output pin changes state when a certain compare match condition occurs. The PWM output function is modified by changing these two bits. It is necessary to only change the values of the CTIO1 and CTIO0 bits only after the CTM has been switched off. Unpredictable PWM outputs will occur if the CTIO1 and CTIO0 bits are changed when the CTM is running.

Bit 3  
CTOC: CTP Output control
0: Initial low
1: Initial high

Compare Match Output Mode
0: Active low
1: Active high

Bit 2  
CTPOL: CTP Output polarity control
0: Non-inverted
1: Inverted

This bit controls the polarity of the CTP output pin. When the bit is set high the CTM output pin will be inverted and not inverted when the bit is zero. It has no effect if the CTM is in the Timer/Counter Mode.

Bit 1  
CTDPX: CTM PWM duty/period control
0: CCRP – period; CCRA – duty
1: CCRP – duty; CCRA – period

This bit determines which of the CCRA and CCRP registers are used for period and duty control of the PWM waveform.

Bit 0  
CTCCLR: CTM Counter Clear condition selection
0: CTMn Comparator P match
1: CTMn Comparator A match

This bit is used to select the method which clears the counter. Remember that the Compact TM contains two comparators, Comparator A and Comparator P, either of which can be selected to clear the internal counter. With the CTCCLR bit set high, the counter will be cleared when a compare match occurs from the Comparator A. When the bit is low, the counter will be cleared when a compare match occurs from the Comparator P or with a counter overflow. A counter overflow clearing method can only be implemented if the CCRP bits are all cleared to zero. The CTCCLR bit is not used in the PWM Mode.
Compact Type TM Operation Modes

The Compact Type TM can operate in one of three operating modes, Compare Match Output Mode, PWM Mode or Timer/Counter Mode. The operating mode is selected using the CTM1 and CTM0 bits in the CTMC1 register.

Compare Match Output Mode

To select this mode, bits CTM1 and CTM0 in the CTMC1 register, should be set to “00” respectively. In this mode once the counter is enabled and running it can be cleared by three methods. These are a counter overflow, a compare match from Comparator A and a compare match from Comparator P. When the CTCCLR bit is low, there are two ways in which the counter can be cleared. One is when a compare match occurs from Comparator P, the other is when the CCRP bits are all zero which allows the counter to overflow. Here both CTMAF and CTMPF interrupt request flags for the Comparator A and Comparator P respectively, will both be generated.

If the CTCCLR bit in the CTMC1 register is high then the counter will be cleared when a compare match occurs from Comparator A. However, here only the CTMAF interrupt request flag will be generated even if the value of the CCRP bits is less than that of the CCRA registers. Therefore when CTCCLR is high no CTMPF interrupt request flag will be generated. If the CCRA bits are all zero, the counter will overflow when its reaches its maximum 10-bit, 3FF Hex, value, however here the CTMAF interrupt request flag will not be generated.

As the name of the mode suggests, after a comparison is made, the CTM output pin will change state. The CTM output pin condition however only changes state when a CTMAF interrupt request flag is generated after a compare match occurs from Comparator A. The CTMPF interrupt request flag, generated from a compare match occurs from Comparator P, will have no effect on the CTM output pin. The way in which the CTM output pin changes state are determined by the condition of the CTIO1 and CTIO0 bits in the CTMC1 register. The CTM output pin can be selected using the CTIO1 and CTIO0 bits to go high, to go low or to toggle from its present condition when a compare match occurs from Comparator A. The initial condition of the CTM output pin, which is setup after the CTON bit changes from low to high, is setup using the CTOC bit. Note that if the CTIO1 and CTIO0 bits are zero then no pin change will take place.
**Compare Match Output Mode – CTCCLR = 0**

Note: 1. With CTCCLR = 0, a Comparator P match will clear the counter
2. The CTM output pin controlled only by CTMAF flag
3. The output pin is reset to its initial state by CTON bit rising edge
**HT45F56 Shock Detector Flash MCU**

**Counter Value**

- 0x3FF: CCRA > 0 Counter cleared by CCRA value
- CCRA = 0 Counter overflow
- CCRA = 0 Counter cleared by CCRA value

**CTCCLR = 1; CTM [1:0] = 00**

**CTON**

- Output pin set to initial Level Low if CTOC=0
- Output Toggle with CTMAF flag
- Output not affected by CTMAF flag, Remains High until reset by CTON bit
- Output Inverts when CTPOL is High
- CTMPF not generated

**CCRA Int. flag CTMAF**

- Output Toggle with CTMAF flag
- Output does not change
- No CTMAF flag generated on CCRA overflow

**CCRP Int. flag CTMPF**

- Output controlled by other pin-shared function
- Output Pin reset to initial state by CTON rising edge
- Output Pin reset to initial state by CTON rising edge

**Compare Match Output Mode – CTCCLR = 1**

- Note: 1. With CTCCLR = 1, a Comparator A match will clear the counter
- 2. The CTM output pin is controlled only by CTMAF flag
- 3. The CTM output pin is reset to initial state by CTON rising edge
- 4. The CTMPF flags is not generated when CTCCLR = 1

---

Rev. 1.20 58 November 26, 2019
Timer/Counter Mode

To select this mode, bits CTM1 and CTM0 in the CTMC1 register should be set to 11 respectively. The Timer/Counter Mode operates in an identical way to the Compare Match Output Mode generating the same interrupt flags. The exception is that in the Timer/Counter Mode the CTM output pin is not used. Therefore the above description and Timing Diagrams for the Compare Match Output Mode can be used to understand its function. As the CTM output pin is not used in this mode, the pin can be used as a normal I/O pin or other pin-shared function.

PWM Output Mode

To select this mode, bits CTM1 and CTM0 in the CTMC1 register should be set to 10 respectively. The PWM function within the CTM is useful for applications which require functions such as motor control, heating control, illumination control etc. By providing a signal of fixed frequency but of varying duty cycle on the CTM output pin, a square wave AC waveform can be generated with varying equivalent DC RMS values.

As both the period and duty cycle of the PWM waveform can be controlled, the choice of generated waveform is extremely flexible. In the PWM mode, the CTCCLR bit has no effect on the PWM operation. Both of the CCRA and CCRP registers are used to generate the PWM waveform, one register is used to clear the internal counter and thus control the PWM waveform frequency, while the other one is used to control the duty cycle. Which register is used to control either frequency or duty cycle is determined using the CTDPX bit in the CTMC1 register. The PWM waveform frequency and duty cycle can therefore be controlled by the values in the CCRA and CCRP registers.

An interrupt flag, one for each of the CCRA and CCRP, will be generated when a compare match occurs from either Comparator A or Comparator P. The CTOC bit in the CTMC1 register is used to select the required polarity of the PWM waveform while the two CTIO1 and CTIO0 bits are used to enable the PWM output or to force the TM output pin to a fixed high or low level. The CTPOL bit is used to reverse the polarity of the PWM output waveform.

If \( f_{SYS} = 8\text{MHz} \), CTM clock source is \( f_{SYS}/4 \), CCRP = 2 and CCRA = 128,
The PWM output frequency = \( (f_{SYS}/4) / (2\times256) \) = \( f_{SYS}/2048 \) = 4 kHz, duty = 128/(2\times256)=25%.

If the Duty value defined by the CCRA register is equal to or greater than the Period value, then the PWM output duty is 100%.

**Programming Considerations**

The TM Counter Registers and the Capture/Compare CCRA registers, all have a low and high byte structure. The high bytes can be directly accessed, but as the low bytes can only be accessed via an internal 8-bit buffer, reading or writing to these register pairs must be carried out in a specific way. The important point to note is that data transfer to and from the 8-bit buffer and its related low byte only takes place when a write or read operation to its corresponding high byte is executed.

As the CCRA registers is implemented in the way shown in the following diagram and accessing these register pairs is carried out in a specific way as described above, it is recommended to use the “MOV” instruction to access the CCRA low byte registers, named CTMAL, using the following access procedures. Accessing the CCRA low byte registers without following these access procedures will result in unpredictable values.

![Diagram of register structure](image)

The following steps show the read and write procedures:

- **Writing Data to CCRA**
  - Step 1. Write data to Low Byte CTMAL
    - note that here data is only written to the 8-bit buffer.
  - Step 2. Write data to High Byte CTMAH
    - here data is written directly to the high byte registers and simultaneously data is latched from the 8-bit buffer to the Low Byte registers.

- **Reading Data from the Counter Registers and CCRA**
  - Step 1. Read data from the High Byte CTMDH or CTMAH
    - here data is read directly from the High Byte registers and simultaneously data is latched from the Low Byte register into the 8-bit buffer.
  - Step 2. Read data from the Low Byte CTMDL or CTMAL
    - this step reads data from the 8-bit buffer.
Digital to Analog Converter

There is a 6-bit R-2R Digital to Analog converter integrated in this device. The digital data to be converted is stored in the DACR register. The D/A converter output can be used as the reference voltage applied on the negative input of the comparator. The DACEN bit is used to control the D/A converter function.

Operational Amplifier

This device contains an operational amplifier with programmable gain selections, which is used to amplify the small analog input signal. After amplification the output signal can be sent to the comparator positive input to compare with the negative input signal. The overall function is controlled by the OPAC and OPGA registers.

Comparators

The device contains an analog comparator which operates with the 6-bit R-2R D/A converter and operational amplifier in applications. These functions offer flexibility via the corresponding registers controlled features such as power-down, hysteresis, etc. In sharing their pins with normal I/O pins the comparator does not waste precious I/O pins if their functions are otherwise unused.

Comparator Block Diagram

Comparator Operation

The comparator functions are used to compare two analog voltages and provide an output based on their input difference. Any pull-high resistors connected to the shared comparator input pins will be automatically disconnected when the corresponding comparator functional pins are selected. As the comparator inputs approach their switching level, some spurious output signals may be generated on the comparator output due to the slow rising or falling nature of the input signals. This can be minimised by the hysteresis function. Ideally the comparator should switch at the point where the positive and negative inputs signals are at the same voltage level. However, unavoidable input offsets introduce some uncertainties here. The hysteresis function, if enabled, will also increase the switching offset value. The hysteresis window will be changed for different selections.

An interrupt will be generated when the comparator output changes state from low to high. Another interrupt will be generated when the comparator output rising edge transition occurs and keeps more than a certain debounce time determined by the DSTAG2–DSTAG0 bits. If the comparator output rising edge transition occurs but does not keep more than the specific debounce time, the debounce circuit interrupt will not be generated.

Comparator Registers

Full control over the internal comparator is provided via the control registers, CMPC, MUXC and DEBC. The comparator output is recorded via a bit in the respective control register. The comparator power down control bit, CMPEN, is used to control the overall comparator function.

Interrupts

Interrupts are an important part of any microcontroller system. When an external event or an internal function such as a Timer Module or an A/D converter requires microcontroller attention, their corresponding interrupt will enforce a temporary suspension of the main program allowing the microcontroller to direct attention to their respective needs. These devices contain several external interrupt and internal interrupts functions. The external interrupts are generated by the action of the external INT0 and INT1 pins, while the internal interrupts are generated by various internal functions such as the TMs, Time Base, EEPROM, Comparator and debounce circuit.

Interrupt Registers

Overall interrupt control, which basically means the setting of request flags when certain microcontroller conditions occur and the setting of interrupt enable bits by the application program, is controlled by a series of registers, located in the Special Purpose Data Memory, as shown in the accompanying table. These registers are the INTC0–INTC2 registers which setup the primary interrupts.

Each register contains a number of enable bits to enable or disable individual interrupts as well as interrupt flags to indicate the presence of an interrupt request. The naming convention of these follows a specific pattern. First is listed an abbreviated interrupt type, then the (optional) number of that interrupt followed by either an “E” for enable/disable bit or “F” for request flag.

**Interrupt Operation**

When the conditions for an interrupt event occur, such as a TM Comparator P or Comparator A or Comparator output transition, etc, the relevant interrupt request flag will be set. Whether the request flag actually generates a program jump to the relevant interrupt vector is determined by the condition of the interrupt enable bit. If the enable bit is set high then the program will jump to its relevant vector; if the enable bit is zero then although the interrupt request flag is set an actual interrupt will not be generated and the program will not jump to the relevant interrupt vector. The global interrupt enable bit, if cleared to zero, will disable all interrupts.

When an interrupt is generated, the Program Counter, which stores the address of the next instruction to be executed, will be transferred onto the stack. The Program Counter will then be loaded with a new address which will be the value of the corresponding interrupt vector. The microcontroller will then fetch its next instruction from this interrupt vector. The instruction at this vector will usually be a JMP which will jump to another section of program which is known as the interrupt service routine. Here is located the code to control the appropriate interrupt. The interrupt service routine must be terminated with a RETI, which retrieves the original Program Counter address from the stack and allows the microcontroller to continue with normal execution at the point where the interrupt occurred.
The various interrupt enable bits, together with their associated request flags, are shown in the accompanying diagrams with their order of priority. Some interrupt sources have their own individual vector while others share the same multi-function interrupt vector. Once an interrupt subroutine is serviced, all other interrupts will be blocked, as the global interrupt enable bit, EMI bit will be cleared automatically. This will prevent any further interrupt nesting from occurring. However, if other interrupt requests occur during this interval, although the interrupt will not be immediately serviced, the request flag will still be recorded.

If an interrupt requires immediate servicing while the program is already in another interrupt service routine, the EMI bit should be set after entering the routine to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the Stack Pointer is decremented. If immediate service is desired, the stack must be prevented from becoming full. In case of simultaneous requests, the accompanying diagram shows the priority that is applied. All of the interrupt request flags when set will wake up the device if it is in SLEEP or IDLE Mode, however to prevent a wake-up from occurring the corresponding flag should be set before the device is in SLEEP or IDLE Mode.

### Comparator Interrupt

The Comparator Interrupt is controlled by the Comparator output transition. A Comparator Interrupt request will take place when the Comparator Interrupt request flag, CPF, is set, which occurs when the Comparator output changes state. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and Comparator Interrupt enable bit, CPE, must first be set. When the interrupt is enabled, the stack is not full and the Comparator output transition occurs, a subroutine call to the Comparator Interrupt vector will take place. When the interrupt is serviced, the Comparator Interrupt flag, CPF, will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.
Debounce Interrupt

The Debounce Interrupt is controlled by the Debounce circuit output transition. A Debounce Interrupt request will take place when the Debounce Interrupt request flag, DEBF, is set, which occurs when the Debounce circuit output changes state. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and Comparator Interrupt enable bit, DEBE, must first be set. When the interrupt is enabled, the stack is not full and the Debounce circuit output transition occurs, a subroutine call to the Debounce Interrupt vector will take place. When the interrupt is serviced, the Debounce Interrupt flag, DEBF, will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.

Time Base Interrupt

The function of the Time Base Interrupt is to provide regular time signal in the form of an internal interrupt. It is controlled by the overflow signal from its internal timer. When this happens its interrupt request flag, TBNF, will be set. To allow the program to branch to its respective interrupt vector addresses, the global interrupt enable bit, EMI and Time Base enable bit, TBnE, must first be set. When the interrupt is enabled, the stack is not full and the Time Base overflows, a subroutine call to its respective vector location will take place. When the interrupt is serviced, the interrupt request flag, TBNF, will be automatically reset and the EMI bit will be cleared to disable other interrupts.

The purpose of the Time Base Interrupt is to provide an interrupt signal at fixed time periods. Its clock source, fTB, originates from the internal clock source fSYS/4 or fTBC and then passes through a divider, the division ratio of which is selected by programming the appropriate bits in the TBC register to obtain longer interrupt periods whose value ranges. The clock source which in turn controls the Time Base interrupt period is selected using the TBCK bit in the TBC register.

### EEPROM Interrupt

The EEPROM Write Interrupt is controlled by the EEPROM Write operation completion. An EEPROM Write Interrupt request will take place when the EEPROM Write Interrupt request flag, DEF, is set, which occurs when an EEPROM Write cycle ends. To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and EEPROM Write Interrupt enable bit, DEE, must first be set. When the interrupt is enabled, the stack is not full and an EEPROM Write cycle ends, a subroutine call to the respective EEPROM Write Interrupt vector will take place. When the EEPROM Write Interrupt is serviced, the Comparator Interrupt flag, DEF, will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.

### TM Interrupts

The Compact TMs have two interrupts, one comes from the comparator A match situation and the other comes from the comparator P match situation. A TM interrupt request will take place when any of the TM request flags are set, a situation which occurs when a TM comparator P or A match situation happens.

To allow the program to branch to its respective interrupt vector address, the global interrupt enable bit, EMI, and respective TM Interrupt enable bit, must first be set. When the interrupt is enabled, the stack is not full and a TM comparator match situation occurs, a subroutine call to the relevant CTM Interrupt vector locations, will take place. When the TM interrupt is serviced, the corresponding CTM interrupt request flag will be automatically cleared. The EMI bit will also be automatically cleared to disable other interrupts.
**Interrupt Wake-up Function**

Each of the interrupt functions has the capability of waking up the microcontroller when in the SLEEP or IDLE Mode. A wake-up is generated when an interrupt request flag changes from low to high and is independent of whether the interrupt is enabled or not. Therefore, even though these devices are in the SLEEP or IDLE Mode and its system oscillator stopped, situations such as external edge transitions on the external interrupt pins, a low power supply voltage or comparator input change may cause their respective interrupt flag to be set high and consequently generate an interrupt. Care must therefore be taken if spurious wake-up situations are to be avoided. If an interrupt wake-up function is to be disabled then the corresponding interrupt request flag should be set high before the device enters the SLEEP or IDLE Mode. The interrupt enable bits have no effect on the interrupt wake-up function.

**Programming Considerations**

By disabling the relevant interrupt enable bits, a requested interrupt can be prevented from being serviced, however, once an interrupt request flag is set, it will remain in this condition in the interrupt register until the corresponding interrupt is serviced or until the request flag is cleared by the application program.

It is recommended that programs do not use the “CALL” instruction within the interrupt service subroutine. Interrupts often occur in an unpredictable manner or need to be serviced immediately. If only one stack is left and the interrupt is not well controlled, the original control sequence will be damaged once a CALL subroutine is executed in the interrupt subroutine.

Every interrupt has the capability of waking up the microcontroller when it is in the SLEEP or IDLE Mode, the wake up being generated when the interrupt request flag changes from low to high. If it is required to prevent a certain interrupt from waking up the microcontroller then its respective request flag should be first set high before enter SLEEP or IDLE Mode.

As only the Program Counter is pushed onto the stack, then when the interrupt is serviced, if the contents of the accumulator, status register or other registers are altered by the interrupt service program, their contents should be saved to the memory at the beginning of the interrupt service routine.

To return from an interrupt subroutine, either a RET or RETI instruction may be executed. The RETI instruction in addition to executing a return to the main program also automatically sets the EMI bit high to allow further interrupts. The RET instruction however only executes a return to the main program leaving the EMI bit in its present zero state and therefore disabling the execution of further interrupts.
Application Circuits

Sense Magnetic Sensor Module Signal by SEN Pin
Instruction Set

Introduction

Central to the successful operation of any microcontroller is its instruction set, which is a set of program instruction codes that directs the microcontroller to perform certain operations. In the case of Holtek microcontroller, a comprehensive and flexible set of over 60 instructions is provided to enable programmers to implement their application with the minimum of programming overheads.

For easier understanding of the various instruction codes, they have been subdivided into several functional groupings.

Instruction Timing

Most instructions are implemented within one instruction cycle. The exceptions to this are branch, call, or table read instructions where two instruction cycles are required. One instruction cycle is equal to 4 system clock cycles, therefore in the case of an 8MHz system oscillator, most instructions would be implemented within 0.5μs and branch or call instructions would be implemented within 1μs. Although instructions which require one more cycle to implement are generally limited to the JMP, CALL, RET, RETI and table read instructions, it is important to realize that any other instructions which involve manipulation of the Program Counter Low register or PCL will also take one more cycle to implement. As instructions which change the contents of the PCL will imply a direct jump to that new address, one more cycle will be required. Examples of such instructions would be "CLR PCL" or "MOV PCL, A". For the case of skip instructions, it must be noted that if the result of the comparison involves a skip operation then this will also take one more cycle, if no skip is involved then only one cycle is required.

Moving and Transferring Data

The transfer of data within the microcontroller program is one of the most frequently used operations. Making use of three kinds of MOV instructions, data can be transferred from registers to the Accumulator and vice-versa as well as being able to move specific immediate data directly into the Accumulator. One of the most important data transfer applications is to receive data from the input ports and transfer data to the output ports.

Arithmetic Operations

The ability to perform certain arithmetic operations and data manipulation is a necessary feature of most microcontroller applications. Within the Holtek microcontroller instruction set are a range of add and subtract instruction mnemonics to enable the necessary arithmetic to be carried out. Care must be taken to ensure correct handling of carry and borrow data when results exceed 255 for addition and less than 0 for subtraction. The increment and decrement instructions INC, INCA, DEC and DECA provide a simple means of increasing or decreasing by a value of one of the values in the destination specified.
Logical and Rotate Operation

The standard logical operations such as AND, OR, XOR and CPL all have their own instruction within the Holtek microcontroller instruction set. As with the case of most instructions involving data manipulation, data must pass through the Accumulator which may involve additional programming steps. In all logical data operations, the zero flag may be set if the result of the operation is zero. Another form of logical data manipulation comes from the rotate instructions such as RR, RL, RRC and RLC which provide a simple means of rotating one bit right or left. Different rotate instructions exist depending on program requirements. Rotate instructions are useful for serial port programming applications where data can be rotated from an internal register into the Carry bit from where it can be examined and the necessary serial bit set high or low. Another application which rotate data operations are used is to implement multiplication and division calculations.

Branches and Control Transfer

Program branching takes the form of either jumps to specified locations using the JMP instruction or to a subroutine using the CALL instruction. They differ in the sense that in the case of a subroutine call, the program must return to the instruction immediately when the subroutine has been carried out. This is done by placing a return instruction "RET" in the subroutine which will cause the program to jump back to the address right after the CALL instruction. In the case of a JMP instruction, the program simply jumps to the desired location. There is no requirement to jump back to the original jumping off point as in the case of the CALL instruction. One special and extremely useful set of branch instructions are the conditional branches. Here a decision is first made regarding the condition of a certain data memory or individual bits. Depending upon the conditions, the program will continue with the next instruction or skip over it and jump to the following instruction. These instructions are the key to decision making and branching within the program perhaps determined by the condition of certain input switches or by the condition of internal data bits.

Bit Operations

The ability to provide single bit operations on Data Memory is an extremely flexible feature of all Holtek microcontrollers. This feature is especially useful for output port bit programming where individual bits or port pins can be directly set high or low using either the "SET [m].i" or "CLR [m].i" instructions respectively. The feature removes the need for programmers to first read the 8-bit output port, manipulate the input data to ensure that other bits are not changed and then output the port with the correct new data. This read-modify-write process is taken care of automatically when these bit operation instructions are used.

Table Read Operations

Data storage is normally implemented by using registers. However, when working with large amounts of fixed data, the volume involved often makes it inconvenient to store the fixed data in the Data Memory. To overcome this problem, Holtek microcontrollers allow an area of Program Memory to be set as a table where data can be directly stored. A set of easy to use instructions provides the means by which this fixed data can be referenced and retrieved from the Program Memory.

Other Operations

In addition to the above functional instructions, a range of other instructions also exist such as the "HALT" instruction for Power-down operations and instructions to control the operation of the Watchdog Timer for reliable program operations under extreme electric or electromagnetic environments. For their relevant operations, refer to the functional related sections.
### Instruction Set Summary

The following table depicts a summary of the instruction set categorised according to function and can be consulted as a basic instruction reference using the following listed conventions.

#### Table Conventions

- `x`: Bits immediate data
- `m`: Data Memory address
- `A`: Accumulator
- `i`: 0–7 number of bits
- `addr`: Program memory address

Note: 1. For skip instructions, if the result of the comparison involves a skip then two cycles are required, if no skip takes place only one cycle is required.
2. Any instruction which changes the contents of the PCL will also require 2 cycles for execution.
3. For the “CLR WDT1” and “CLR WDT2” instructions the TO and PDF flags may be affected by the execution status. The TO and PDF flags are cleared after both “CLR WDT1” and “CLR WDT2” instructions are consecutively executed. Otherwise the TO and PDF flags remain unchanged.
Instruction Definition

**ADC A,[m]**  
Add Data Memory to ACC with Carry  
Description: The contents of the specified Data Memory, Accumulator and the carry flag are added. The result is stored in the Accumulator.  
Operation:  
\[ \text{ACC} \leftarrow \text{ACC} + [m] + C \]  
Affected flag(s): OV, Z, AC, C

**ADCM A,[m]**  
Add ACC to Data Memory with Carry  
Description: The contents of the specified Data Memory, Accumulator and the carry flag are added. The result is stored in the specified Data Memory.  
Operation:  
\[ [m] \leftarrow \text{ACC} + [m] + C \]  
Affected flag(s): OV, Z, AC, C

**ADD A,[m]**  
Add Data Memory to ACC  
Description: The contents of the specified Data Memory and the Accumulator are added. The result is stored in the Accumulator.  
Operation:  
\[ \text{ACC} \leftarrow \text{ACC} + [m] \]  
Affected flag(s): OV, Z, AC, C

**ADD A,x**  
Add immediate data to ACC  
Description: The contents of the Accumulator and the specified immediate data are added. The result is stored in the Accumulator.  
Operation:  
\[ \text{ACC} \leftarrow \text{ACC} + x \]  
Affected flag(s): OV, Z, AC, C

**ADDM A,[m]**  
Add ACC to Data Memory  
Description: The contents of the specified Data Memory and the Accumulator are added. The result is stored in the specified Data Memory.  
Operation:  
\[ [m] \leftarrow \text{ACC} + [m] \]  
Affected flag(s): OV, Z, AC, C

**AND A,[m]**  
Logical AND Data Memory to ACC  
Description: Data in the Accumulator and the specified Data Memory perform a bitwise logical AND operation. The result is stored in the Accumulator.  
Operation:  
\[ \text{ACC} \leftarrow \text{ACC} \text{ "AND" } [m] \]  
Affected flag(s): Z

**AND A,x**  
Logical AND immediate data to ACC  
Description: Data in the Accumulator and the specified immediate data perform a bitwise logical AND operation. The result is stored in the Accumulator.  
Operation:  
\[ \text{ACC} \leftarrow \text{ACC} \text{ "AND" } x \]  
Affected flag(s): Z

**ANDM A,[m]**  
Logical AND ACC to Data Memory  
Description: Data in the specified Data Memory and the Accumulator perform a bitwise logical AND operation. The result is stored in the Data Memory.  
Operation:  
\[ [m] \leftarrow \text{ACC} \text{ "AND" } [m] \]  
Affected flag(s): Z
### CALL addr

**Description**
Unconditionally calls a subroutine at the specified address. The Program Counter then increments by 1 to obtain the address of the next instruction which is then pushed onto the stack. The specified address is then loaded and the program continues execution from this new address. As this instruction requires an additional operation, it is a two cycle instruction.

**Operation**
- Stack ← Program Counter + 1
- Program Counter ← addr

**Affected flag(s)**
None

### CLR [m]

**Description**
Each bit of the specified Data Memory is cleared to 0.

**Operation**
[m] ← 00H

**Affected flag(s)**
None

### CLR [m].i

**Description**
Bit i of the specified Data Memory is cleared to 0.

**Operation**
[m].i ← 0

**Affected flag(s)**
None

### CLR WDT

**Description**
The TO, PDF flags and the WDT are all cleared.

**Operation**
- WDT cleared
- TO ← 0
- PDF ← 0

**Affected flag(s)**
TO, PDF

### CLR WDT1

**Description**
The TO, PDF flags and the WDT are all cleared. Note that this instruction works in conjunction with CLR WDT2 and must be executed alternately with CLR WDT2 to have effect. Repetitively executing this instruction without alternately executing CLR WDT2 will have no effect.

**Operation**
- WDT cleared
- TO ← 0
- PDF ← 0

**Affected flag(s)**
TO, PDF

### CLR WDT2

**Description**
The TO, PDF flags and the WDT are all cleared. Note that this instruction works in conjunction with CLR WDT1 and must be executed alternately with CLR WDT1 to have effect. Repetitively executing this instruction without alternately executing CLR WDT1 will have no effect.

**Operation**
- WDT cleared
- TO ← 0
- PDF ← 0

**Affected flag(s)**
TO, PDF

### CPL [m]

**Description**
Each bit of the specified Data Memory is logically complemented (1’s complement). Bits which previously contained a 1 are changed to 0 and vice versa.

**Operation**
[m] ← [m]

**Affected flag(s)**
Z
CPLA [m]
Description: Complement Data Memory with result in ACC
Each bit of the specified Data Memory is logically complemented (1's complement). Bits which previously contained a 1 are changed to 0 and vice versa. The complemented result is stored in the Accumulator and the contents of the Data Memory remain unchanged.
Operation: ACC ← [m]
Affected flag(s): Z

DAA [m]
Description: Decimal-Adjust ACC for addition with result in Data Memory
Convert the contents of the Accumulator value to a BCD (Binary Coded Decimal) value resulting from the previous addition of two BCD variables. If the low nibble is greater than 9 or if AC flag is set, then a value of 6 will be added to the low nibble. Otherwise the low nibble remains unchanged. If the high nibble is greater than 9 or if the C flag is set, then a value of 6 will be added to the high nibble. Essentially, the decimal conversion is performed by adding 00H, 06H, 60H or 66H depending on the Accumulator and flag conditions. Only the C flag may be affected by this instruction which indicates that if the original BCD sum is greater than 100, it allows multiple precision decimal addition.
Operation: [m] ← ACC + 00H or [m] ← ACC + 06H or [m] ← ACC + 60H or [m] ← ACC + 66H
Affected flag(s): C

DEC [m]
Description: Decrement Data Memory
Data in the specified Data Memory is decremented by 1.
Operation: [m] ← [m] − 1
Affected flag(s): Z

DECA [m]
Description: Decrement Data Memory with result in ACC
Data in the specified Data Memory is decremented by 1. The result is stored in the Accumulator. The contents of the Data Memory remain unchanged.
Operation: ACC ← [m] − 1
Affected flag(s): Z

HALT
Description: Enter power down mode
This instruction stops the program execution and turns off the system clock. The contents of the Data Memory and registers are retained. The WDT and prescaler are cleared. The power down flag PDF is set and the WDT time-out flag TO is cleared.
Operation: TO ← 0
PDF ← 1
Affected flag(s): TO, PDF

INC [m]
Description: Increment Data Memory
Data in the specified Data Memory is incremented by 1.
Operation: [m] ← [m] + 1
Affected flag(s): Z

INCA [m]
Description: Increment Data Memory with result in ACC
Data in the specified Data Memory is incremented by 1. The result is stored in the Accumulator. The contents of the Data Memory remain unchanged.
Operation: ACC ← [m] + 1
Affected flag(s): Z

</table>
**RET A,x**

Return from subroutine and load immediate data to ACC

**Description**
The Program Counter is restored from the stack and the Accumulator loaded with the specified immediate data. Program execution continues at the restored address.

**Operation**
Program Counter ← Stack
ACC ← x

**Affected flag(s)**
None

**RETI**

Return from interrupt

**Description**
The Program Counter is restored from the stack and the interrupts are re-enabled by setting the EMI bit. EMI is the master interrupt global enable bit. If an interrupt was pending when the RETI instruction is executed, the pending Interrupt routine will be processed before returning to the main program.

**Operation**
Program Counter ← Stack
EMI ← 1

**Affected flag(s)**
None

**RL [m]**

Rotate Data Memory left

**Description**
The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0.

**Operation**
[m].(i+1) ← [m].i; (i=0~6)
[m].0 ← [m].7

**Affected flag(s)**
None

**RLA [m]**

Rotate Data Memory left with result in ACC

**Description**
The contents of the specified Data Memory are rotated left by 1 bit with bit 7 rotated into bit 0. The rotated result is stored in the Accumulator and the contents of the Data Memory remain unchanged.

**Operation**
ACC.(i+1) ← [m].i; (i=0~6)
ACC.0 ← [m].7

**Affected flag(s)**
None

**RLC [m]**

Rotate Data Memory left through Carry

**Description**
The contents of the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7 replaces the Carry bit and the original carry flag is rotated into bit 0.

**Operation**
[m].(i+1) ← [m].i; (i=0~6)
[m].0 ← C
C ← [m].7

**Affected flag(s)**
C

**RLCA [m]**

Rotate Data Memory left through Carry with result in ACC

**Description**
Data in the specified Data Memory and the carry flag are rotated left by 1 bit. Bit 7 replaces the Carry bit and the original carry flag is rotated into the bit 0. The rotated result is stored in the Accumulator and the contents of the Data Memory remain unchanged.

**Operation**
ACC.(i+1) ← [m].i; (i=0~6)
ACC.0 ← C
C ← [m].7

**Affected flag(s)**
C

**RR [m]**

Rotate Data Memory right

**Description**
The contents of the specified Data Memory are rotated right by 1 bit with bit 0 rotated into bit 7.

**Operation**
[m].i ← [m].(i+1); (i=0~6)
[m].7 ← [m].0

**Affected flag(s)**
None
RRA [m]  Rotate Data Memory right with result in ACC
Description  Data in the specified Data Memory and the carry flag are rotated right by 1 bit with bit 0
rotated into bit 7. The rotated result is stored in the Accumulator and the contents of the
Data Memory remain unchanged.
Operation  ACC.i ← [m].(i+1); (i=0~6)
            ACC.7 ← [m].0
Affected flag(s)  None

RRC [m]  Rotate Data Memory right through Carry
Description  The contents of the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0
replaces the Carry bit and the original carry flag is rotated into bit 7.
Operation  [m].i ← [m].(i+1); (i=0~6)
            [m].7 ← C
            C ← [m].0
Affected flag(s)  C

RRCA [m]  Rotate Data Memory right through Carry with result in ACC
Description  Data in the specified Data Memory and the carry flag are rotated right by 1 bit. Bit 0 replaces
the Carry bit and the original carry flag is rotated into bit 7. The rotated result is stored in the
Accumulator and the contents of the Data Memory remain unchanged.
Operation  ACC.i ← [m].(i+1); (i=0~6)
            ACC.7 ← C
            C ← [m].0
Affected flag(s)  C

SBC A,[m]  Subtract Data Memory from ACC with Carry
Description  The contents of the specified Data Memory and the complement of the carry flag are
subtracted from the Accumulator. The result is stored in the Accumulator. Note that if the
result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is
positive or zero, the C flag will be set to 1.
Operation  ACC ← ACC − [m] − C
Affected flag(s)  OV, Z, AC, C

SBCM A,[m]  Subtract Data Memory from ACC with Carry and result in Data Memory
Description  The contents of the specified Data Memory and the complement of the carry flag are
subtracted from the Accumulator. The result is stored in the Data Memory. Note that if the
result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is
positive or zero, the C flag will be set to 1.
Operation  [m] ← ACC − [m] − C
Affected flag(s)  OV, Z, AC, C

SDZ [m]  Skip if decrement Data Memory is 0
Description  The contents of the specified Data Memory are first decremented by 1. If the result is 0 the
following instruction is skipped. As this requires the insertion of a dummy instruction while
the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program
proceeds with the following instruction.
Operation  [m] ← [m] − 1
            Skip if [m]=0
Affected flag(s)  None
SDZA \([m]\)  
**Description** The contents of the specified Data Memory are first decremented by 1. If the result is 0, the following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0, the program proceeds with the following instruction.

**Operation**  
\[
\text{ACC} \leftarrow [m] - 1
\]
Skip if ACC=0

**Affected flag(s)** None

SET \([m]\)  
**Description** Each bit of the specified Data Memory is set to 1.

**Operation**  
\[
[m] \leftarrow \text{FFH}
\]

**Affected flag(s)** None

SET \([m].i\)  
**Description** Bit \(i\) of the specified Data Memory is set to 1.

**Operation**  
\[
[m].i \leftarrow 1
\]

**Affected flag(s)** None

SIZ \([m]\)  
**Description** The contents of the specified Data Memory are first incremented by 1. If the result is 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program proceeds with the following instruction.

**Operation**  
\[
[m] \leftarrow [m] + 1
\]
Skip if [m]=0

**Affected flag(s)** None

SIZA \([m]\)  
**Description** The contents of the specified Data Memory are first incremented by 1. If the result is 0, the following instruction is skipped. The result is stored in the Accumulator but the specified Data Memory contents remain unchanged. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program proceeds with the following instruction.

**Operation**  
\[
\text{ACC} \leftarrow [m] + 1
\]
Skip if ACC=0

**Affected flag(s)** None

SNZ \([m].i\)  
**Description** If bit \(i\) of the specified Data Memory is not 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is 0 the program proceeds with the following instruction.

**Operation**  
\[
\text{Skip if } [m].i \neq 0
\]

**Affected flag(s)** None

SUB A,[m]  
**Description** The specified Data Memory is subtracted from the contents of the Accumulator. The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

**Operation**  
\[
\text{ACC} \leftarrow \text{ACC} - [m]
\]

**Affected flag(s)** OV, Z, AC, C
**SUBM A,[m]**  Subtract Data Memory from ACC with result in Data Memory

**Description**  The specified Data Memory is subtracted from the contents of the Accumulator. The result is stored in the Data Memory. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

**Operation**  
\[ [m] \leftarrow ACC - [m] \]

**Affected flag(s)**  
OV, Z, AC, C

---

**SUB A,x**  Subtract immediate data from ACC

**Description**  The immediate data specified by the code is subtracted from the contents of the Accumulator. The result is stored in the Accumulator. Note that if the result of subtraction is negative, the C flag will be cleared to 0, otherwise if the result is positive or zero, the C flag will be set to 1.

**Operation**  
\[ ACC \leftarrow ACC - x \]

**Affected flag(s)**  
OV, Z, AC, C

---

**SWAP [m]**  Swap nibbles of Data Memory

**Description**  The low-order and high-order nibbles of the specified Data Memory are interchanged.

**Operation**  
\[ [m].3\sim[m].0 \leftrightarrow [m].7\sim[m].4 \]

**Affected flag(s)**  
None

---

**SWAPA [m]**  Swap nibbles of Data Memory with result in ACC

**Description**  The low-order and high-order nibbles of the specified Data Memory are interchanged. The result is stored in the Accumulator. The contents of the Data Memory remain unchanged.

**Operation**  
\[ ACC.3\sim ACC.0 \leftarrow [m].7\sim[m].4 \]
\[ ACC.7\sim ACC.4 \leftarrow [m].3\sim[m].0 \]

**Affected flag(s)**  
None

---

**SZ [m]**  Skip if Data Memory is 0

**Description**  If the contents of the specified Data Memory is 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program proceeds with the following instruction.

**Operation**  
Skip if \([m]=0\)

**Affected flag(s)**  
None

---

**SZA [m]**  Skip if Data Memory is 0 with data movement to ACC

**Description**  The contents of the specified Data Memory are copied to the Accumulator. If the value is zero, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0 the program proceeds with the following instruction.

**Operation**  
\[ ACC \leftarrow [m] \]

**Affected flag(s)**  
None

---

**SZ [m].i**  Skip if bit i of Data Memory is 0

**Description**  If bit i of the specified Data Memory is 0, the following instruction is skipped. As this requires the insertion of a dummy instruction while the next instruction is fetched, it is a two cycle instruction. If the result is not 0, the program proceeds with the following instruction.

**Operation**  
Skip if \([m].i=0\)

**Affected flag(s)**  
None
**TABRD [m]**

**Description**
The low byte of the program code (specific page) addressed by the table pointer pair (TBHP and TBLP) is moved to the specified Data Memory and the high byte moved to TBLH.

**Operation**

\[
\begin{align*}
[m] & \leftarrow \text{program code (low byte)} \\
\text{TBLH} & \leftarrow \text{program code (high byte)}
\end{align*}
\]

**Affected flag(s)**
None

**TABRDC [m]**

**Description**
The low byte of the program code (current page) addressed by the table pointer (TBLP) is moved to the specified Data Memory and the high byte moved to TBLH.

**Operation**

\[
\begin{align*}
[m] & \leftarrow \text{program code (low byte)} \\
\text{TBLH} & \leftarrow \text{program code (high byte)}
\end{align*}
\]

**Affected flag(s)**
None

**TABRDL [m]**

**Description**
The low byte of the program code (last page) addressed by the table pointer (TBLP) is moved to the specified Data Memory and the high byte moved to TBLH.

**Operation**

\[
\begin{align*}
[m] & \leftarrow \text{program code (low byte)} \\
\text{TBLH} & \leftarrow \text{program code (high byte)}
\end{align*}
\]

**Affected flag(s)**
None

**XOR A,[m]**

**Description**
Data in the Accumulator and the specified Data Memory perform a bitwise logical XOR operation. The result is stored in the Accumulator.

**Operation**

\[
\text{ACC} \leftarrow \text{ACC "XOR"}[m]
\]

**Affected flag(s)**
Z

**XORM A,[m]**

**Description**
Data in the specified Data Memory and the Accumulator perform a bitwise logical XOR operation. The result is stored in the Data Memory.

**Operation**

\[
\begin{align*}
[m] & \leftarrow \text{ACC "XOR"}[m]
\end{align*}
\]

**Affected flag(s)**
Z

**XOR A,x**

**Description**
Data in the Accumulator and the specified immediate data perform a bitwise logical XOR operation. The result is stored in the Accumulator.

**Operation**

\[
\text{ACC} \leftarrow \text{ACC "XOR" x}
\]

**Affected flag(s)**
Z
